斗 and 升 are small volume units for measuring grain. Token (30) therefore refers to the scarcity of financial resources. This can be viewed as a metaphor with a metonymic motivation: Since water is such an essential life-supporting substance and hence standing for it (metonymic relation), it is further extended to financial resources in general, as (30) can be said without any reference to water.

3.3. Movement Is Water

To the Chinese mind, water is a symbol of change, as is seen in a popular saying:

(31)
 山 不 转 水 转
 Mountain not moving water moving
 ‘Mountain is stationary; water is ongoing’

This metaphor is used to speak about the didactic nature of stability versus change: Some things in life are stable and others are ever changing and evolving. Since water is such a prominent element of nature, its attribute of fluidity serves as a natural (in both senses of the word) motivation for the metaphor MOVEMENT IS WATER.

Token (32) is based on the MOVING TRAFFIC IS MOVING WATER metaphor, whereby flowing water and flying dragons create an image of non-stopping heavy traffic.

(32)
 车 水 马 龙
 vehicle water horse dragon
 ‘Vehicles are like flowing water and horses are like flying dragons’

In (33), 水 refers to life-supporting materials:

(33)
 细 水 长 流
 small water long flow
 ‘Careful spending makes resources last longer.’

This token maps the moving nature of water to a simple principle of financial management: If one controls the flow of water, the water will run longer; if one controls spending, the resources will last longer. Hence what underlies (33) seems to be the metaphor (RUNNING) ECONOMIC RESOURCE IS MOVING WATER.

The movement of water can be smooth. The smoothness of flowing water has hence been transferred to a number of specific sub-domains. Token (34), for instance, invites us to see the smoothness and naturalness of a writer's prose style in terms of flowing water (SMOOTH STYLE IS MOVING WATER).

(34)

行 云 流 水

Floating cloud flowing water

'(a style of writing that is) smooth and natural, like floating clouds and flowing water'

When it comes to oratorical skills, it is the forcefulness of the movement of water that is mapped to the target domain, motivating the metaphor ELOQUENCE IS RUSHING WATER:

(35)

悬 河 泻 水

hanging river rush water

'fluent and eloquent like rushing water'

悬河 'hanging river' refers to a body of water that experiences a sudden drop of elevation, such as a waterfall. The movement of water in a "hanging river" is hence forceful, as indicated by 泻水 'rushing water'. Thus, unlike (34), which stresses the smoothness of moving water, (35) foregrounds its characteristics of rhythm, forcefulness, and voluminousness.

As we have seen in this section, the super target domain of MOVEMENT consists of sub-domains that differ from each other in two ways.

First is the *kind* of things: there is traffic; there is financial resource; there is prose style; there is eloquence.

Second, the different aspects of water's movement have been captured to motivate these seeming disparate set of metaphors: its constancy, its smoothness, and its unstoppableity.

3.4. Power Is Water

Flowing water generates power. Hence the metaphorical extension of WATER to MOVEMENT could be an intermediary between the source domain of WATER and the target domain of POWER. I start with (36), a well-known scholarly phrase:

(36)

水 可 载 舟 亦 可 覆 舟
 Water can carry boat, too can overturn boat
 ‘Water can keep a boat afloat; it can also overturn it’

This saying talks about the two aspects of the power of the masses: They can topple a ruling class as well as support it. The token as a whole maps WATER to MASSES, under which are a number of sub-mappings: GOVERNMENT IS BOAT; SUPPORTIVE POWER OF MASSES IS SUPPORTIVE POWER OF WATER; DESTRUCTIVE POWER OF MASSES IS DESTRUCTIVE POWER OF WATER. Further, the DIRECTION OF MASSES’ WILL IS THE DIRECTION OF THE WATER FLOWING. So, if the government goes with the masses’ will, it will be supported by the masses. Otherwise, it will be overthrown by the masses.

Unlike (36), which invokes the image of power in its sheer force—a boat is overturned mostly by water moving with high speed due to the difference of elevation in its bed or to violent waves caused by air turbulences—(37), below, is motivated by water’s power of persistence:

(37)

水 滴 石 穿
 water drip stone chisel-through
 ‘Constant dripping of water chisels through a rock’

Under what seems to be the overarching metaphor EFFORT IS WATER, small amounts of effort are seen as drops of dripping water that is usually inconsequential in a short period of time.

However, if the effort is consistently applied, it will lead to success in the same way dripping water “chisels through a rock.”⁵

The power of water is also seen as being capable of making things happen naturally. Token (38), for example, speaks of a goal being achieved because its external conditions are met:

(38)

水 到 渠 成
 water arrive channel appear
 ‘Where water arrives, a channel is formed’

In other words, EXTERNAL CONDITION (FOR GOAL) IS WATER; CHANNEL IS GOAL. Since the flowing of water makes a channel without effort—via its natural flowing—this token is used to dispense the wisdom that one should not force things to happen.

Now, consider the following that speak to the destructive power of water:

⁵ Note that there is an equivalent saying in English: Constant dripping wears a stone. While the English version also speaks to water’s persistence, the verb, wear, lacks the sense of power and volition that are present in its Chinese counterpart, 穿 ‘chisel through’.

(39)

洪	水	橫	流
flood	water	over	flow

‘Evil prevails’

The destructive power in the target domain EVIL is mapped onto water out of human control in the source domain FLOOD.

Token (40) combines FLOOD with BEASTS to denote awesome power:

(40)

洪	水	猛	兽
flood	water	savage	east

‘frightful disasters’

Instead of flood, (41) depicts disasters in terms of sea water:

(41)

海	水	群	飞
sea	water	together	fly

‘great turmoil’

Again, the motivation for these phrases appears to be the out-of-control-ness of water.

3.5. Purity Is Water

To the naked eye, water is transparent and colorless. These two characteristics could be the motivation for WATER to be extended to the domain PURITY. Tokens for this extension fall into three kinds: those that describe beauty, those that describe the heart, and those that describe friendship. I start with tokens that describe beauty:

(42)

水	灵
water	clever

‘beautiful and bright’

(43)

水	汪	汪
Water	full	full

‘bright (and intelligent) eyes’

These two expressions can only be used to describe pre-teen children (possibly also adolescents in some dialects). The sense of beauty thereby conveyed is not only looks—general appearance in (42) and eyes in (43)—but also, and more importantly, the innocence

that is seen in a young person, untainted by adult desires and complications. Hence the metaphor that underlies these two expressions is BEAUTY OF PURITY IS WATER.

How can the heart be a target domain of WATER, then? The answer may lie in the transparency of water. Hence there exist tokens such as (41), motivated by the metaphor (CLEAR) HEART IS WATER:

(44)

白	水	鉴	心
white	water	reflect	heart

‘heart as clear as water’

The last sub-domain of PURITY, friendship, is illustrated by (44):

(45)

淡	水	交情
thin	water	friendship

‘friendship as clear and transparent as water’

In a Chinese context, such a “thin-water” friendship is one that is built on mutual admiration, respect, and loyalty. It is “thin-water” because there is no need to consolidate it through the exchange of material goods. The phrase 君子之交淡如水 ‘Friendship between gentlemen is like water’ and many other similes support this PURE FRIENDSHIP IS (THIN) WATER metaphor.

3.6. Woman Is Water

The metaphorical extension of WATER to WOMAN seems to have its basis in the Taoist *yin yang* dichotomy, as both water and woman belong to *yin* (as opposed to mountain and man, their respective *yang* counterparts). In (46), the phrase 弱水 ‘soft water’ refers to women in general:

(46)

弱	水	三	千	我	只	取一瓢	饮
fragile	water	three	thousand	I	only	take one-cup	drink

‘Among so many women, I only choose/need one to love.’

which instantiates the metaphor WOMAN IS SOFT WATER, linked by a correspondence between the soft texture of water and the perceived softness and fragility of a woman.

Autumn water, 秋水, is believed to be water of the most limpid kind. The phrase 秋水 is therefore used to refer to the eyes of a woman, particularly in sayings like (46):

(47)

望	穿	秋	水
gaze	wear-out	autumn	water

‘Long gazing with expectation (for her man’s return) wears out a woman’

Or to the woman herself:

(48)

秋	水	伊	人
autumn	water	nice	lady

‘Nice ladies are limpid water’

Next, WOMAN is mapped onto WATER and MAN to FISH via the relationship between water and fish. Consider (49), in which the wife is referred to as water and the husband, fish:

(49)

鱼	水	和	谐
fish	water	together	harmony

‘harmony of husband and wife’

This expression is partially motivated by the extension of WATER to LIFE SUSTAINER. In our discussion of that extension (Section 3.2), life refers to all forms of life. In (49), the life sustaining characteristic of water is specified into the immediate essential environment for fish: While non-maritime life relies on water primarily for hydration, fish relies on water for respiration because of its anatomy (breathing through the gills rather than the lungs).

If (49) invokes the image of the close relationship between fish and water and the reliance of the former on the latter, (50) invokes more of an image of fish swimming in water:

(50)

鱼	水	之	欢
fish	water	of	merriment

‘merriment of a man and/in a woman’

This expression is a standard euphemism for the sexual relationship or a sexual encounter between a man and woman. Its sexual meaning is arrived at via an invitation to think about 鱼 ‘fish’ as being inside 水 ‘water’. To anticipate our discussion below, (50) also reflects sexism: If the merriment of a sexual encounter is mapped to the swimming of fish in water whereby fish enjoys far more “merriment” than water, who the “beneficiary” of such a relationship is supposed to be is obvious.

Token (51) further illustrates the belief that women are the object of enjoyment for men:

(51)

山 温 水 软

Mountain warm water soft

‘The mountains are warm and the water is soft’

The adjectives 温 ‘warm’ and 软 ‘soft’, particularly when used together in a phrase like (51), ascribe attributes to a woman’s body. Another such phrase is 温香软玉 “warm fragrance and soft jade,” referring to the warmth and fragrance the woman’s body is supposed to provide. The expression in (51), therefore, has come to refer to a sensually intoxicating environment, most often one in which a man gets “lost”—losing his will and ambition. Quite clearly, (51) is also motivated by the extension of WATER to NATURE discussed in Section 3.1, as a sensual environment such as a woman’s body can be seen as the extension of nature through analogy: Woman’s body is to sexual enjoyment as water is to nature.

Token (52) is used to describe a woman’s promiscuity:

(52)

水 性 杨 花

water feature poplar flower

‘changeable and floating characteristics’

A promiscuous woman is seen in terms of water because water has no fixed home—it flows freely and “guiltlessly” to wherever lower in elevation—and it has no shape of its own—it takes on the shape of any container it happens to be in. She is also a poplar flower because poplar flower, due to its light weight, flies everywhere in breeze.

If the sexist nature of the previous examples is striking, (53) is more so, as it simply *states* that women are trouble, a manifestation of the metaphor BEAUTY IS DISASTROUS WATER:

(53)

红 颜 祸 水

rosy cheek disastrous water

‘beauty is the source of disaster’

which is related to examples motivated by the destructive power of water I discussed in Section 3.3. Chinese history records several instances whereby an emperor indulged himself in a beauty and neglected his governing duties, leading to the suffering of his subjects and the demise of his empire. These failures are attributed to the temptation by women, as is clearly suggested by (53).

4. SUMMARY DISCUSSION

In Section 2, I discussed how the WATER radical functions to organize Chinese words into a network of networks in the orthography. In Section 3, I referred to Nie and Chen [2008], demonstrating how the notion of WATER has been extended to six target domains via six super metaphors at the level of phrases. These two networks, however, are networks of the same super-network, a web of notions connected together at different levels, via different motivations, and on different dimensions, but all based on the notion of WATER. This has been the first aim of the present paper.

The significance of discovering this complicated network of networks goes beyond the the discovery itself. It offers us much about the architecture of language, particularly the relationship between language on the one hand and the mind and society on the other. The foregoing discussions, for instance, have demonstrated how words with WATER radicals and phrases with 水 are motivated by a host of factors, some ontological, some perceptual, some grammatical, while others societal. Although these factors interconnect, interact and may even intertwine to a point where things are difficult to sort out, there seems to have emerged a general trend. At the level of the radical, motivational factors appear to have more to do with the interaction of speakers with the physical world. At the level of phrase, societal factors—social practices, history, and cultural values—begin to exert themselves.

At the outset of the paper, I indicated that the present study will raise issues about Chinese morphology and morphology. The heart of these issues, to reiterate, is a discrepancy between two received motions. On the one hand, linguists recognize the value of the radical in the Chinese orthography. On the other hand, they do not assign any linguistic status to the radical. The radicals, for instance, are not seen as morphemes, although they have identifiable meanings or functions, for the sole reason that they are part of the orthography, and orthography is viewed as no more than a record of language, not the language itself.

However, the fact that the radical represents meaning or function probably should not be brushed off thus easily. After all, radicals *are* units of the Chinese word, helping the (literate) speaker to organize their lexicon. True, the existence of the radical does not have psychological reality in the mind of the illiterate. But—allow me to sound unduly argumentative—the radicals were first designed by none other than those who did *not* read or write: Most certainly, there was nobody who could read or write without an orthography to read or write in! Moreover, what would we as linguists say when most if not all speakers of Chinese become literate? I have no answer to these or any other related questions. I only believe they are important for the study of Chinese and encourage interested colleagues to ponder: “What are the radicals doing in the Chinese language?”

Chapter 73

CONSTRUAL OPERATIONS OF THE ENGLISH PROGRESSIVE CONSTRUCTION

*Kim Ebensgaard Jensen**

Institute of Culture and Global Studies. Aalborg University, Denmark

ABSTRACT

The progressive construction has a tripartite symbolic structure in which the auxiliary verb symbolically links up with the meaning component of TENSE, the main verb with the expressed SITUATION, and the present participial realization of the main verb with the aspectual category of IMPERFECTIVITY. The present paper focuses on each of these symbolic links and their interplay, and investigates the meaning construction processes involved in the symbolic structure of the progressive construction. Drawing on Croft and Wood's [2000] model of construal operations—revised in Croft and Cruse [2004: 40–73]—the present paper provides an overview of construal operations that are likely to be at play in the construction of the aspectual and actional meaning components of the progressive construction. The discussion also involves instances of the progressive construction, which display low semantic compatibility, as the ensuing semantic coercion involves a number of construal operations that are revelatory to the meaning construction of the progressive in general.

Keywords: aspect, Aktionsart, coercion, construal operations, construction grammar

1. INTRODUCTION

The primary function of the English progressive construction is to express imperfective aspect. It is well known that aspect is a matter of completion or incompleteness of the situation expressed by a sentence, and that, while the perfective aspect adds a sense of completion to the situation in question, the imperfective aspect adds a sense of ongoingness. While the

progressive construction itself has received a lot of attention, both in terms of its form and semantics as well as in terms of its historical development and grammaticalization, there are not many systematic studies of the semantic processes of meaning construction associated with it.

The present paper investigates the English progressive construction in the perspective of cognitive linguistics and construction grammar so as to provide an overview of its meaning components and the semantic processes involved in the construction of its content. The central theoretical concepts in the present discussion are construal (which, in cognitive linguistics, is held to be the central ingredient in linguistic meaning constructing),¹ construal operations (which are the processes involved in the construction of linguistic meaning), and the notion of grammatical constructions as central symbolic units of language. The main premise of the present discussion is that constructional meaning, like lexical meaning, is construed and that certain construal processes are conventionally associated with constructions. Drawing on a model of construal operations proposed by Croft and Wood [2000; Croft and Cruse 2004: 40–73], I suggest a number of specific construal operations that are likely to be involved in the meaning constructing of the English progressive construction.

The present article is structured as follows. The notions of construal and construal operation are explained in section two, while section three sketches out the idea of the grammatical construction as a conventionalized semiotic unit in language. This is essentially the usage-based take on construction grammar associated with Croft's [2001, 2005] Radical Construction Grammar, in which constructions are meaningful and functional holistic units that emerge in the grammatical system through use in discourse. In sections four and five, I discuss the meaning components and meaning constructing associated with the English progressive construction, suggesting a set of construal operations that are likely to be conventionally associated with the progressive construction. Section five focuses on instances of the progressive construction that involve semantic incompatibility between the main verb and the construction itself. Such incompatibility calls for reconstrual of the verb such that it conforms with the semantics of the construction, and such reconstrual provides some very useful hints as to which processes of meaning constructing are likely to be associated with the construction.

2. CONSTRUAL OPERATIONS

2.1. Construal and Meaning Constructing

Construal is an essential ingredient in meaning constructing and draws upon encyclopedic knowledge and psychological processes of interpretation and conceptualization [e.g., Croft and Cruse 2004: 40–73, 141–163; Croft and Wood 2000; Fillmore 1977, 1982; Langacker 1987, 1991; Talmy 2000a, 2000b; Verhagen 2004] rather than upon a repertoire of specifically linguistic concepts and rules. While construal has to do with meaning, Langacker [1993: 447] argues for a distinction between content and construal since expressions with the

¹I use the term “meaning constructing” with reference to what is traditionally called “meaning construction” so as not to create unnecessary confusion about the terms “(grammatical) construction”, “construal”/“construing”, and “meaning construction”.

same content may display differences in semantics, because they construe the content differently. This is reflected in, for example, voice alteration where the active and passive impose different perspectives on the situation in question, without actually changing the expressed state-of-affairs, but there are also cases in which differing construals of the situation result in differences that go beyond mere perspectivization. Countability and uncountability, for instance, may result in very different construals of otherwise similar scenarios, as in *There was a cat on the road* versus *There was cat on the road*. The former contains an indefinite article which signals countability and thus refers to the cat as one unit with clearly defined demarcations, while the latter, which makes use of a zero-article and thus signals uncountability, construes the cat as a mass-like entity, probably referring to the remains of a road-killed cat.

What allows for the construal of the cat as an intact cat is that certain grammatical expressions, such as the indefinite article, numerals, and plural forms, are conventionally associated with construal processes that conceptualize the nominal referent as a clearly demarcated unit which can be differentiated from its surroundings and others of its kind. On the other hand, the non-intactness of the cat in the second example is attributable to the use of zero-articles with singular forms which in English is conventionally associated with construal processes that conceptualize the referent of the noun phrase in question as a mass-like entity with weakly defined, or non-defined, internal and external boundaries. Linguistic convention is not just a matter of certain semantic content being associated with certain linguistic forms; it is also a matter of certain construal processes that have become associated with linguistic expressions through frequency of use, and this is what results in a sense of stability in the symbolic relation between form and content and also allows for dynamism and variation between different instances of occurrence of the same linguistic unit.

2.2. Croft and Wood's Model of Construal Operations

Construal is a dynamic constructive process and involves a plethora of mental operations, and, since linguistic meaning is a matter of construal, en- and decoding involves processes which are similar, or even identical, to processes that are involved in general human cognition [Croft and Wood 2000: 52-53, 55]. The following section provides an overview of such processes, or construal operations, drawing mainly on the inventory of operations proposed by Croft and Wood [2000] and revised by Croft and Cruse [2004: 40-73], which in turn draws on the conceptual systems proposed by Fillmore [1977, 1982], Lakoff [1987], Lakoff and Johnson [1980], Langacker [1987, 1991] and Talmy's [2000a].

There are four main categories of construal operations, each of which represents a basic cognitive ability pertaining to a specific area of experience (attention/salience, judgment/comparison, perspective/situatedness, and constitution/gestalt) which will be described in the following sections. These will be explained in the following sections.

2.2.1. Attention/Salience

Attention/salience covers construal operations that relate to one's ability to establish, maintain, and shift one's attention and distribute one's focus on various details of a scene.

Selection is a type of an attention-related construal operation, which draws on the ability to focus one's attention towards one or more parts of a scene, while removing one's attention

from other parts which are not, for whatever reason, salient. The selected part is profiled [Langacker 1987: 118] while the rest of the scene is gapped [Talmy 2000a: 259]. The gapped parts do not disappear, they are just outside the immediate scope of attention. Selection is mainly deployed in cognition through the profiling, or selection, of certain parts of a cognitive model, such as the type of structure that Fillmore [1977, 1982] refers to as a semantic frame and what Langacker [1987, 1993, 2001a, 2001b] calls a domain or a base.² A frame is a cognitive structure which is based on patterns of recurring experiences in interacting with the world and organizes concepts that are experienced together into a holistic structure:

By the term 'frame' I have in mind any system of concepts related in such a way that to understand any one of them you have to understand the whole structure in which it fits; when one of the things in such a structure is introduced into a text, or into a conversation, all of the others are automatically made available. [Fillmore 1982: 111].

Profiling is ubiquitous in language, and most lexemes in a lexical field based on a semantic frame profile various parts of that frame. For instance, the nouns *buyer* and *seller* profile the main AGENTIVE roles in the COMMERCIAL TRANSACTION frame, while the verbs *cost*, *sell*, and *charge* profile relations and perspectivize acts in the frame [Croft et al. 2001].

Metonymy is another type of construal operation which involves selection: the most salient part of a scenario is selected such that it represents the entire scenario. We see this in the morphological process of conversion of nouns into verbs without derivational affixation, in which the referent of the noun in question is profiled and used with reference to the entire activity, the referent being deemed the most salient part, as in *The crowd were bottling the band*, in which the INSTRUMENT, the BOTTLES, is profiled and then promoted to being the representative of that entire situation. Metonymy is closely related to the primary psychological process of *pars pro toto* in which a part of an entity or scene is perceived as being identical to that entity or scene [Jacobsen 1971: 20] and may even be an instance of that process.

Attention/salience also covers the ability to take a fine-grained view or a coarse-grained view on the scene or parts of the scene, the ability to dynamically scan the scene or to statically view it in its entirety, and the ability to construe a static scene dynamically through fictive motion. There are two types of scanning [Langacker 1987: 144–146]: summary scanning (the construal of a dynamic scene in its entirety as a holistic entity without internal temporal relations) and sequential scanning (the construal of a scene as an event, or a series of events, unfolding in conceived time). Linguistically, scanning depends on choice of word class and both inflectional and derivational morphology: finite verbs and verb phrases scan the expressed situation sequentially while deverbal nouns and noun phrases scan it summarily as in *Boston Bridge collapsed* versus *the collapse of Boston Bridge* [Langacker 1987: 144–146]. In the former, a temporal relation is imposed on the collapse of the bridge such that it is construed as an event that unfolds 'step by step' along a linear time-line from the inception of the collapse to the point when the bridge has collapsed completely, while in the latter there is no such temporal relation.

²For the sake of simplicity, I shall stick primarily to Fillmore's model of frame semantics in the remainder of this paper.

2.2.2. Judgment/Comparison

Judgment/comparison covers construal operations that compare experiences in terms of similarities and differences, such as operations of categorization and figurative comparison like metaphor and simile. Construals of judgment/comparison are likely to be related to the primary psychological process which Jacobsen [1971: 19] refers to as the principle of similarity being equal to identity, according to which similarities between two experiences may be so salient that the experiences in question are perceived as being, if not identical, then at least members of the same category.

Perhaps surprisingly, figure-ground alignment [Rubin 1915] is listed in Croft and Wood's [2000: 62] model of construal operations under judgment rather than perspective, but, as they argue, referring to Langacker [1987: 121–122], figure-ground alignment is based, not only on perspective, but primarily on the comparison of parts of the scene in question in terms of salience such that a part that is considered salient stands out as the figure, while a part that is considered non-salient serves as the ground.

2.2.3. Perspective/Situatedness

Perspective/situatedness covers construal operations that allow individuals to relate to the scene or context they find themselves in; in essence, the construals of perspective/situatedness construct the scene, its relations, and the situatedness of the conceptualizer (including the relation, or state, of existence itself) and relate to “the philosophical notion of our situatedness in the world in a particular location—where location must be construed broadly to include temporal, epistemic and cultural context as well as spatial location” [Croft and Cruse 2004: 58].

An important mental ingredient in situatedness is what Langacker [1987: 122–123] calls viewpoint:

For many types of conception—particularly those grounded in visual experience—the importance of viewpoint is self-evident. We can look at a physical object from different sides (front/back, top/bottom, etc.), and what we actually see varies accordingly. In observing a complex scene with multiple participants, we can assume different positions in relation to them, with direct consequences for their perceived proximity and salience. The effects of variable viewpoint on actual (peripherally connected) visual experience are duplicated in autonomous processing (i.e., visual imagery); thus I can close my eyes and visualize what an object looks like when seen from different angles. [Langacker 1987: 122–123].

Closely related to viewpoint is deixis, which covers those units of language that situate the discourse in context. Croft and Wood's [2000] model includes deixis as a matter of construal, classifying the traditional deictic categories (person deixis, temporal deixis, spatial deixis) as spatiotemporal deixis. In addition, common ground is included as a category under deixis, called epistemic deixis, which covers construals that relate the discourse to the shared, or presumably shared, cultural, social, mental and encyclopedic contexts. Deictic construals establish, or draw on, perspectives in the context of the discourse with the communicative situation itself, or the deictic center, as the view point.

Empathy is also included as a type of perspectival construal, which allows the speaker to latch on to various participants in the scene and empathize with them. An important factor in

perspectival construals, and specifically in empathy, is what Langacker [1993: 451] calls mental transfer, “in which the conceptualizer imagines (or at least takes into account) how the scene appears to some other observer”, thus allowing the speaker to construe a scene in the perspective of a vantage point that does not correspond to the speaker’s own origo, or deictic center.

Finally, subjectivity and objectivity are listed as perspectival construal operations in Croft and Wood’s [2000] model, and are defined by Langacker [2001a: 25] as follows:

In both perception and conception, entities are construed with varying degrees of subjectivity/objectivity. As I understand these terms, an entity is construed objectively to the extent that it is onstage as a focused object of viewing. It is construed subjectively to the extent that it remains offstage as the implicit subject of viewing.

2.2.4. Constitution/Gestalt

Constitution/gestalt covers construal operations that interpret the constitution of entities in terms of both their shape and physical, temporal and other features as well as their internal and external topological, meronomic, and geometrical structures. The construal operations of constitution/gestalt thus conceptualize an entity as a holistic unit or as a non-unit, and even chains or series of dynamic actions as constituting one event, and represent “the most basic level of *constituting* experience and giving it a structure or a *Gestalt*” [Croft and Wood 2000: 67, italics in original]. This sort of construal involves structural schematization, which specifies the structure of entities and their components. Among other things, structural schematization allows for the individuation of an entity in terms of boundedness. Individuation is pivotal in, for example, the distinction between countable and uncountable nouns, since countable nouns in the plural, such as *leaves*, refer to multiple individuated entities, while uncountable nouns, such as *foliage*, express masses of non-individuated material. From Croft and Cruse’s [2004: 63] reference to Talmy [2000a: 47–68], I understand that the many factors of configurational structure in Talmy’s system are considered construal operations of individuation in Croft and Wood’s [2000] model of construal operations. Talmy’s categories of configurational structure, which are discussed in neither Croft and Wood [2000] nor Croft and Cruse [2004], are listed here.

Plexity is whether an entity consists of just one element, in which case we speak of uniplexity, or multiple equal elements, in which case we speak of multiplexity. Plexity is at play in grammatical number, as the singular form construes the referent as uniplex, and the plural form construes it as multiplex. The process of multiplexing is the construal process behind multiplex construals. Plural forms are but one type of expression that is conventionally associated with multiplexing; another example of a multiplexing construction is the catenative verb construction, as in *She kept sighing* [Talmy 2000a: 48]. The reverse process whereby uniplex units are construed is called unit excerpting [Talmy 2000a: 49] and is associated with singular forms and measure phrase constructions, as in *furniture* versus *a piece of furniture*.

Boundedness has to do with the construction of boundaries for the entity in question. The processes behind boundedness and unboundedness construals are called portion excerpting (or bounding) and debounding respectively [Talmy 2000a: 51–52]. One type of construction which is associated with portion excerpting is the preposition phrase structure [*in* NP_{EXTENT-OF-TIME}] as in *She dressed in five minutes*, which sets up a bounded period of time

[Talmy 2000a: 51]. Measure phrases can also be used to construe bounded units as in *a cup of water*.

State of dividedness is the internal segmentation of an entity, which may be composite or continuous. A composite entity is one whose internal structure involves breaks or interruptions, while a continuous one is one whose structure is not fragmented in any conceivable sense. The mental process of discretizing interprets otherwise continuous entities as composite. The opposite process is called melding [Talmy 2000a: 56]. According to Talmy [2000a: 56], there may be no overt grammatical means of discretizing or melding in English, but certain lexical forms, such as *particles* in the measure expression *particles of water*, can break down the referent into aggregates of smaller components, while lexical expressions such as *walk* and *breathe* refer to activities that meld together smaller actions (*walk* refers to a series of steps, and *breathe* to a series of inhalation-exhalation sequences). Melding also seems to be a matter of degree [Talmy 2000a: 56–57], with lexically melding forms like *walk* and *breathe* construing entities that display a higher degree of continuity than cases where some additional linguistic material do the melding, as in *masses of leaves* versus *foliage*. *Foliage* can be grouped with the verbs *walk* and *breathe* as expressions that evoke what Talmy [2000a: 56] calls spontaneous melding.

The degree of extension of an entity covers its extension in space or time, or both. There are three categories here: point (which takes up so little space or time that it cannot be perceived as an extent at all), bounded extent (which takes up a perceivable amount of time and space, but which is also delimited by a boundary), and unbounded extent (which is an infinite quantity). These categories are linguistically reflected in the lexemes *speck*, *ladder* and *river* respectively [Talmy 2000a: 61]. The mental process of reduction [Talmy 2000a: 62] allows for the adoption of a distal perspective in which the referent is construed as bounded and reduced in degree of extension while magnification allows for the adoption of a proximal perspective in which the referent is construed as unbounded and the degree of extension is increased. For example, *She climbed the fire ladder* construes the situation as a bounded extent delimited by the bottom and the top of the fire ladder, while *Moving along on the training course, she climbed the fire ladder at exactly midday* construes the climb up the ladder as being point durational seen against the backdrop of all the activities on the training course, and *She kept climbing higher and higher up the fire ladder as we watched* construes it as an unbounded extent [Talmy 2000a: 61–62]. As these examples show, the categories of boundedness and degree of extension are intertwined, and how they also depend on viewpoint location and proximity.

The category of pattern of distribution refers to the internal structure of events, and is essentially Talmy's [2000a: 63] version of *Aktionsart* [e.g., Bache 1997: 231–243, Bache and Davidsen-Nielsen 1997: 191–195; Croft MS: §2]. Talmy's categories are one-way nonresettable, one-way resettable, full-cycle, multiplex, steady-state and gradient actions. All of Talmy's categories correspond to categories that have been extensively investigated, and labeled, in the study of *Aktionsart*. A one-way nonresettable event corresponds to an irreversible telic punctual process, while the one-way resettable event corresponds to a reversible one. The full-cycle category corresponds to a reversible process, which is one that automatically resets to the initial state-of-affairs, and the multiplex process corresponds to an iterative process. The steady state situation corresponds to a state, and the gradient category corresponds to a non-punctual telic or directed process. The importance of Talmy's contribution to *Aktionsart* is that it places *Aktionsart* under the rubric of structural

configuration and thus allows for the analysis of the expression of events through language in terms of constitution/gestalt.

The axiality of an entity covers its scalar properties, and axiality could thus be included under Croft and Cruse's [2004: 65] grouping of construal operations relating to scale. For instance, many gradable adjectives express an attribute which can be conceptualized in terms of an axis or a scale of degree. There are also lexical sets, or semantic fields, which pertain to a semantic frame whose basic structure as a scalar one, such as *poor*, *wealthy*, *rich* and related lexemes. The category of scene partitioning has to do with the conception of an entire scene in terms of its parts and participants. Scene partitioning is captured in Croft and Wood's [2000] model under the category of force dynamics along with Talmy's [2000a: 509–549] systems of force dynamics and causation.

In addition to Talmy's categories, many of the laws and principles of gestalt formation discussed by gestalt psychologists Koffka [1935] and Köhler [1947] may be included as construal operations, or construal factors, under the heading of structural schematization. Constitution/gestalt also subsumes relationality, or entity/interconnection, covering construals of the relational and non-relational properties of the entities in question.

2.2.5. *Construal Co-Operation*

Construal operations are held to co-operate, as it were, such that the constructing of one meaning component involves not just one, but several construal operations. We shall see this in relation to the construction of imperfectivity, which involves several construal operations. As hinted at, the construal-based view of meaning implies that one goes beyond what is traditionally considered linguistic meaning, taking a broader perspective on the relation between communication and cognition, such that meaning subsumes:

- (i) both established and novel conceptions; (ii) not only abstract or intellectual 'concepts' but also immediate sensory, motor, and emotive experience; (iii) conceptions that are not instantaneous but change or unfold through processing time; and (iv) full apprehension of the physical, social, and linguistic context. [Langacker 2001b: 252].

If one buys into this view of meaning, the construal operations in meaning construction of any type of linguistic unit are cognitively complex processes that draw on general cognitive processes and structures.

3. GRAMMATICAL CONSTRUCTIONS AND THE PROGRESSIVE CONSTRUCTION

One of the basic tenets of cognitive linguistics and usage-based linguistics is that linguistic meaning is not as such encoded in any fixed way in the linguistic signs of the language system, but rather construed online in discourse in accordance with the general principles of human cognition. Construal in linguistic communication is subject to constraints in the contexts in which discourse takes place, including discursive conventions [Croft and Cruse 2004: 141–192; Cruse 2000a, 2000b, 2002].

It is convention that contributes stability to the linguistic system in the sense that, through patterns of regular use, certain construals become associated with certain linguistic signs via various processes of conventionalization. With Croft and Wood's [2000] model of construal operations in mind and the central role which construal is given in meaning, conventional linguistic meaning involves sets of construal operations that are conventionally associated with the linguistic form in question, such that interlocutors will arrive at similar contents whenever they use the same linguistic form.

It is not just lexemes and morphemes that express conventional meaning, so do grammatical constructions. In construction grammar [e.g., Fillmore et al. 1988; Goldberg 1995; Croft 2001], constructions are not just functional units in grammar, but also basic units of language. The present discussion of the English progressive construction is essentially a constructionist one, my focus being on the relationship of meaning constructing between the form of a construction and the semantics of instances of the construction in use. The main premise of the present discussion is the basic tenet of construction grammar that constructions are pairings of form and conventional meaning which, like other semiotic units, are entrenched in the speech community in question. The relationship between form and meaning is held to to essentially be the same as with lexical and morphological units, and constructional meaning is constructed in accordance with the same principles as lexical and morphological meaning. Constructions may be simple, consisting of just one unit (and, in that sense, lexemes and morphemes are also constructions), or complex, consisting of more units. Complex constructions can be compositional such that each of the units a complex construction consists of may express its own meaning component, forming an intraconstructional symbolic unit, but it cannot be reduced to primitive, independent meaning atoms [Croft 2001: 47].

Based on the observation that constructions, like lexemes, express semantic content, construction grammarians have gone as far as posing a lexicon-syntax continuum [Croft 2001: 17; Goldberg 1995: 7] to replace the Generativist idea of lexicon and syntax being two separate components of language with only syntax being considered part of grammar. The English progressive construction is a complex construction, consisting of a form of *BE*, as the auxiliary verb, and a main verb in the present participial form. The auxiliary verb *BE* specifies tense in finite instances of the progressive construction, while the present participle form of the main verb expresses the imperfective aspect.

The lexeme that takes up the main verb function specifies the imperfectivized situation itself. The basic progressive construction has three main semantic areas: TENSE, IMPERFECTIVE aspect and the SITUATION itself. Each of these areas contains a number of semantic units that are essential to the overall meaning of the English progressive construction, and each enters into semantic linkage with a formal element. Thus, *BE* forms a symbolic unit with TENSE, while the verb itself forms a symbolic unit with the SITUATION component and the morphological realization of the main verb as a present participle links up with the component of IMPERFECTIVITY. If Croft and Wood's [2000] model of construal operations is applied to constructional meaning, constructions, like lexemes, will be conventionally associated with construal operations. This means that each meaning component of a complex construction involves a set of construal operations.

4. CONSTRUCTING THE MEANING OF THE PROGRESSIVE CONSTRUCTION

4.1. Imperfectivity

As opposed to a perfective one, an imperfective situation has not been completed or terminated, but is still ongoing or progressing. As Bache [1997: 271] notes, “[w]ith the perfective aspect, one thus gets a sense of situational *completeness* whereas with the imperfective aspect one gets a sense of situational *progression*” (italics in original). Bache [1997: 269] himself suggests that aspect is a matter of applying a situational focus to the event, and that grammatical subcategories of aspect correspond to different patterns of inclusion of parts into, and exclusion of parts from, the situational focus. In Bache’s approach, imperfectivity consists in a situation being viewed such that its INCEPTION and TERMINATION are excluded from the situational focus, while the MIDDLE PHASE, in which the situation unfolds, is included. This is a matter of attention/salience, since one directs one’s attention to the MIDDLE PHASE of the event in question, gapping the INCEPTION and TERMINATION.

Bache’s [1997] situational scope corresponds to profiling in Langacker’s work and Croft and Woods’ [2000] model of construal operations. Aspect, I believe, involves a generalized semantic frame of the situation structure. This generalized event frame, or aspectual frame, which is specifically associated with the progressive construction has been described to some extent by Suzuki [1996: 267–268], who further describes it as a gestalt which is more basic than the parts it consists of, and in a specifically constructionist perspective by Michaelis [1998].

The aspectual frame has a simple structure, as it consists of the three said phases, and is conventionally associated with aspectual constructions in general. The semantic difference between the English aspectual constructions lies in different profiling patterns. The English progressive construction, through convention, profiles the MIDDLE PHASE, while the perfective profiles all phases. In addition, it could be argued [Michaelis 1998: 84–87] that constructions like [*START/BEGIN to V*] and [*BEGIN V-ing*] express the inceptive aspect in which the INCEPTION is profiled. Likewise, an expression like [*STOP V-ing*] could be argued to express a terminative aspect in which only the TERMINATION is profiled.

Given that verb phrases express events through the propositional act function of predication [Searle 1969: 22–53; 77–96; 97–127], the semantic content of verb phrases that relates to the internal structure and mechanics of the SITUATION, is prototypically not stative but dynamic. Consequently, the English progressive construction, which is of course a verb phrase construction, involves dynamic attention in the form of sequential scanning. Sequential scanning of an event is the interpretation of a situation as unfolding over perceived time, and it seems logical to assume that, in order for a process to be construed as ongoing, it should be dynamically unfolding over time.

Rather than operating with the definitions of perfectivity as equalling dynamicity and imperfectivity as equalling stativity, as proposed by Langacker [1987: 254–257], I shall, following Bache [1997] and Bache and Davidsen-Nielsen [1997: 194–196], separate aspect from actionality, or *Aktionsart*, and operate with them as two different, but related, categories. Aspect is primarily a matter of viewing specifications, while stativity and dynamicity

are considered *Aktionsart* categories having to do with the inner mechanics and make-up of situations. As it happens, stativity and dynamicity are the superordinate categories within *Aktionsart*:

The primary ontological division in this hierarchy [the inventory of *Aktionsart* categories] has an epistemological basis: states are those situations whose existence can be verified on the basis of a momentuous 'sample', while event verification requires tracking over time. [Michaelis 2004: 63].

The main distinction among *Aktionsarten* falls between states and events, or processes, and, in the framework of the present discussion, these do not equal imperfectivity and perfectivity, although, as we shall see, aspect and *Aktionsart* are closely related.

The progressive construction involves not only construal operations of attention/salience, but also of constitution/gestalt, since, as I have just suggested, the attention-based conceptualizations impose certain construals of constitution upon the event itself. One could argue that the progressive construction involves gestalts at a basic semantic level, in that the aspectual frame could be described as a gestalt, whose parts are functionally defined from the whole they appear in [Suzuki 1996: 167–168]; this is also very much in line with Fillmore's [1982: 111] holistic definition of semantic frames. In that respect gestalt is unavoidable as a semantic factor, but that is not the constitution/gestalt-related issue I am going to discuss here, as I shall focus on construals of the situation itself.

There is one constitution/gestalt construal that is invariably imposed upon the event by the progressive construction, which logically follows from the profiling of the unfolding MIDDLE PHASE, and gapping of the INCEPTION and TERMINATION. Given the exclusion of the INCEPTION and TERMINATION from the situational focus, the progressive construction construes the event in question as an unbounded one, since those phases serve not just as parts of the event, but also demarcate it from whatever comes before and after it; in that sense, they are situational boundaries. Consider the following examples:

- (1) a. But oh we were told about the war and what was happening between the Germans and
whatnot. (BNC HEC 154).
- b. Yes but you see at this time the girl took up her tea tray and, and when she took, she
knocked on the door and when she opened the door the Manageress was lying on
the
floor foaming at the mouth, she'd had a heart attack. (BNC HDJ 286).
- c. When you are talking to a teacher in school, you speak and act in a different way
from when you are talking to your friends out of school. (BNC G3P 3015).

The sentences in (1a) and (1b), which contain the past progressive, express situations that are in progress at the point in the past at from which they are viewed. The sentence in (1c) contains two instances of the present progressive, both of which present the situation of talking in a specific way as ongoing at the present moment. The situation in (1c) is a generic, universally true, one, but it construed as if it were a specific more tangible process. In all three examples, the situations are not bounded by the INCEPTION and TERMINATION, because

these are outside of the situational focus. There is no overt mention of how what was happening with the Germans in (1a) was initiated or terminated, and, in (1b), we are told nothing of how the manageress ended up lying on the floor, or how her lying on the floor was terminated (although we can infer from the mention of her heart attack that she must have fallen). In (1c), we are given an *in medias res* perspective on two situations of talking with no overt mention of the initiation or termination of the two generalized conversations.

Bounding is, as Langacker also points out, one of the main semantic distinguishing features that separate imperfectivity from perfectivity [Langacker 1987: 258–262]. As Langacker [2001b: 259] states, “[i]ntuitively, we can describe the progressive in terms of ‘zooming in’ and taking an ‘internal view’ of a bounded event. Technically, I describe it as imposing an immediate scope that excludes the endpoints of the perfective process.” While the profiling of the MIDDLE PHASE logically results in the construal of the situation as unbounded, the INCEPTION and TERMINATION do not disappear from the cognitive landscape, as they are still present in the scope of attention of the situation (and, if the imperfective situation has natural inception and termination points, then they can be inferred, and might even be considered presuppositions).

The scope of attention is defined by Langacker [1987: 118] as “those portions of a scene that it specifically involves”, and can easily be accessed and profiled by other construction in the same discourse. Scope of attention is also listed as a construal operation of attention/salience in Croft and Cruse’s [2004: 50–51] revised version of Croft and Wood’s [2000] model of construal operation, and they describe its relation to selection thus: “The second aspect of attention is that the focus of attention—what is being selected—is surrounded by a scope of attention, that is, a periphery of consciousness where entities are accessible to attention” [Croft and Cruse 2004: 50, boldface in original]. In the progressive construction, the entire aspectual frame forms the scope of attention of the profiled MIDDLE PHASE and the INCEPTION and TERMINATION of the process, while excluded from the situational focus through gapping, are still present in the scope of attention. They are retrievable through discourse as illustrated by the following example (which is not from the corpus):

- (2) When I entered the room, they were still talking. They kept talking till the sun came up and then they went to bed, having discussed politics since noon.

The progressive *were talking* presents the conversation as being in process and imposes the imperfective profiling pattern upon it. While never overtly expressed, the TERMINATION of the conversation can be retrieved via *till the sun came up*, which implies that the conversation was terminated at that point, while the understanding of the adverbial clause *having discussed politics since noon* draws on the INCEPTION.

The occurrence of the presupposition-triggering catenative verb construction [KEEP V-ing] in *kept talking* also draws on the presence of the INCEPTION in the scope of attention, as it presupposes that the process has already been initiated. In addition to selection and bounding, and as a logical consequence of these, viewpoint proximity is also involved in the meaning constructing of imperfectivity in that, in order to take the internal view that focuses on the MIDDLE PHASE and excludes the two other phases, one must adopt a proximal perspective, which the perfective profiling pattern, which has all three phases in the situational focus, requires the adoption of a distal perspective.

Another constitution/gestalt-related construal which seems to invariably apply with the progressive construction has to do with degree of extension, as the situation is set up as a durative one. Durative situations correspond to bounded and unbounded extents. Punctual situations, situations which correspond to Talmy's notion of a point, are too brief for there to be identified as containing MIDDLE PHASES. Therefore, when verbs that usually express punctual situations are used with the progressive, they are reconstrued into displaying a perceptible degree of extension [see also Givón 1993: 153–160]:

- (3) a. Yeah, come down with the stairs to chap, young chap, I told you he's knocking on the door, it must of been then. (BNC KBE 9765).
- b. Nicholas Ferrar died in 1637. As he was dying, he urged the family to continue in "the good old way" of the primitive Church which they had revived together. (BNC CFF 939).
- c. Oh, excuse me a minute, my little chaplain is jumping up and down, splattering the parchment with ink. (BNC H90 2291).

All three verbs in the examples in (3) typically predicate acts which are temporally brief, or punctual, but, in (3), they appear in the progressive construction, and, thus, in (3a) and (3c), the otherwise punctual situations of knocking and jumping are reconstrued as temporally extensive iterative series of repeated knocking and repeated jumping, while, in (3b), the punctual process of dying is expanded into a durative situation in which the process of changing from being ALIVE to being DEAD is presented as a gradual one.

4.2. Tense

Tensed instances of the progressive construction involve a set of construal operations which are essentially independent of the imperfective aspect, as tense and aspect are two separate grammatical and cognitive categories; tense construals apply to any tensed verb phrase and not just the progressive construction, aspect (being a question of profiling and gapping phases of the internal mechanics of the situation) is primarily a matter of attention/salience and constitution/gestalt while tense is a matter of perspective/situatedness, the primary function being the location of the situation in time relative to the communicative situation [e.g., Michaelis 1998: 2]. Aspect is the relation of the event or some part of it to its own internal temporal progression, while tense is its relation to the temporal environment in and around the discourse. Since tense, after all, contributes to the overall meaning of a tensed instance of the progressive construction, I will briefly account for construal operations in the meaning constructing of tense here.

Given that tense undoubtedly draws on temporal deixis [Comrie 1985: 14; Lyons 1968: 305, 1977: 677–690], tense is a construal of perspective/situatedness and falls under Croft and Wood's (2000) category of spatiotemporal deixis. Langacker [2001b: 260] emphasizes the deictic nature of tense and its relation to the situatedness of the discourse situation itself:

I describe a tense marker as imposing an immediate temporal scope which is located with respect to the time of speaking (unlike the immediate scope imposed by the progressive). In particular, past tense specifies that this immediate scope is prior to the time of speaking, while the present tense (at least in English) specifies that it precisely coincides with the time of speaking.

This is cognitively analogous to looking at the visual physical context; that is, looking backwards, forwards and at one's own location, which seems to be supported by the TIME IS A MOVING OBJECT and TIME IS STATIONARY AND WE MOVE THROUGH IT metaphors of English [Lakoff and Johnson 1980: 42–44] both of which involve a linear conceptualization of time in English.

I would further suggest that temporal deixis involves a more or less engrained cognitive structure that structures the linear experience of time, which is a quite simple frame consisting of the linearly related concepts PAST, PRESENT and FUTURE. In addition to being linearly structured, the cognitive structure is, as suggested by Ota [1963: 19], also a gestalt:

“Now” is either the moment of speaking or any length of time including the moment of speaking and flanked by the past and the future. These two conditions are necessary to define “now”; if the timespan does not include the moment of speaking, it is not “now”, and if it is not in contrast with the past and the future, it becomes timeless.

This frame is applied in the construal of time and imposes temporal relations upon the external world, and perspectivizes the context temporally with the now as the temporal deictic center.

Tensed verb phrases simply profile the relevant part of the frame such that past tense verb phrases profile the PAST component of the frame while present tense ones profile the PRESENT component and future indicating verb phrases profile the FUTURE component. In the English progressive construction, the imperfective event is located in a period in time that corresponds to the profiled part of the temporal frame. On this definition, the perspectivizing situatedness of temporal deixis interplays with selection from the domain of attention/salience.

4.3. The Situation Itself

As we have already seen, the English progressive construction imposes construals of constitution/gestalt upon the situation expressed by the main verb in terms of boundedness and degree of extension. What about the structural schematization of the event itself?

While to some extent specifying *Aktionsart*, or, in Talmian terminology, patterns of distribution, the English progressive construction does not as such contribute greatly to the scene partitioning, or force dynamics, of the event, since such details are specified by the main verb in conjunction with the argument structure.

Boundedness and degree of extension have counterparts in Talmy's [2000a: 63] system of patterns of distribution, as the punctual situation, a point in the system of degree of extension, corresponds to a one-way situation (a temporally brief one) while gradient situations (non-punctual telic ones) correspond to bounded extents in the degree of extension system, and steady states correspond to on unbounded extents.

I have already argued that the English progressive imposes construals of extension, or durativity, and unboundedness upon the situation, while the perfective, in contrast, construes the situation as bounded, as it includes the *TERMINATION* phase in the situational focus. There is another relevant construal operation from the system of patterns of distribution. The progressive construes the event as a dynamic one, and, consequently, steady states are not expressed by the English progressive construction. The logic here is quite clear: an imperfective situation is one which unfolds through time and is construed as ongoing; in a steady state, there are no changes, and, since the main relation is a static one, there is nothing going on in a steady state, and, since nothing is going on, it cannot be construed as ongoing. Thus, the progressive construction actually has one *Aktionsart* specification in terms of force dynamics, albeit a minute one: there has to be some sort of energy input and some sort of *AGENTIVE* role to provide the dynamics that enable the situation to be unfolding and construable as ongoing. The other patterns of distribution, such as cyclicity, reversibility, multiplexity and so on, are fairly irrelevant to the English progressive construction as such, but some of them do come into play in cases where the main verb does not conventionally express the same semantic situational details as the construction does.

As a minor point, it should be mentioned that the progressive construction, like all other verb phrase constructions, specifies the entity/interconnection of the predicated event as a relational one, since situations predicated by verbs set up relations between entities in the scene, which are referred to by nominal sentence arguments.

4.4. Construal Operations and Symbolic Structure

The English progressive construction contains three symbolic links, each of which combines a formal element with a semantic component. The auxiliary *BE* links up with the semantic component of *TENSE*, while the main verb, through lexical specification, links up with that of the situation itself. The morphological specification of the main verb as a present participle links up with the semantic component of *IMPERFECTIVITY* [see also Kirsner and Thompson 1976: 216-7; Verspoor 1996: 438].

Each of the three semantic components is established through meaning constructing and involves a number of construal operations which are conventionally associated with the progressive construction. The present discussion has focused on these construal operations, which can now be related to the overall symbolic structure of the progressive construction.

The attention/salience-based construal operations of profiling, scope of attention and dynamic attention as well as viewpoint along with the constitution/gestalt-based construal operation of boundedness are associated with the symbolic relation between the present participial realization of the verb and the semantic component of *IMPERFECTIVITY*. The imperfective aspect is constructed through profiling of the *MIDDLE PHASE* in the aspectual frame while the *INCEPTION* and *TERMINATION* phases are gapped, but still retained in the scope of attention and may be retrieved or profiled at any point during the discourse. Moreover, the sequential scanning of the process presents it as unfolding over time and thus allows for the construal of it as ongoing. As a consequence of the profiling of the *MIDDLE PHASE*, the process is unbounded, since the *INCEPTION* and *TERMINATION* are in essence the parts of the process that serve as the boundaries of the process. This viewing arrangement presupposes proximity between the viewpoint and the event.

The constitution/gestalt-based operations of degree of extension, patterns of distribution and force dynamics as well as relational entity/interconnection all apply to the construal of the event itself when expressed in the progressive construction and thus relate to the symbolic link between the main verb and the semantic component of the SITUATION. Given that the process has to be temporally extended for the aspectual frame to be applicable, it has to display a considerable degree of extension. Likewise, in order for the situation to be construed as unfolding over time and thus sequentially scanned, there has to be some sort of dynamicity to it, and thus the pattern of distribution has to be a non-stative one, and, in terms of force dynamics, there has to be some sort of AGENTIVE role to provide an energy input. Boundedness, which follows as a consequence of imperfectivity is of course also a matter of the constitution/gestalt of the SITUATION itself, and, consequently, there is an internal non-monadicity [Bache 1997: 159-166] in the symbolic structure of the progressive construction, as there is symbolic linkage between both the lexical main verb itself and its present participial realization through the operation of unbounding. Through the verbal propositional act function of predication [Searle 1969: 22-53; 77-96; 97-127], the progressive construction also specifies relational entity/interconnection.

Finally, the component of TENSE involves temporal deixis, which belongs in the realm of perspective/situatedness, and, if one buys the idea of a temporal frame that structures the experience of time, also profiling.

5. CONSTRUAL OPERATIONS AND COERCION IN THE PROGRESSIVE CONSTRUCTION

The construal operations of the progressive construction are especially evident in instances of the construction occurring with semantically incompatible verbs that undergo coercion in order to become semantically more similar to the construction.

5.1. Coercion

Coercion is perhaps best understood in relation to semantic compatibility which is when there is semantic overlap or lack of mutual semantic conflict between an expression and the linguistic context in which it occurs. Thus, there is semantic compatibility between a word and the construction it appears in if there is semantic overlap, or lack of mutual conflict, between the conventionalized meaning of the word and the conventionalized meaning of the construction. Semantic compatibility is a matter of degree: the higher the degree of compatibility between a word and a construction, the higher the probability of the word appearing in that construction [Stefanowitch and Gries 2005: 4]. Coercion arises in cases of low semantic compatibility and is a type-shifting process whereby the nature of a linguistic unit is altered such that the degree of compatibility between the unit and the context, in this case the construction is increased [e.g., de Swart 2003; Francis and Michaelis 2003; Michaelis 2003, 2004]

Constructional coercion is thus a process of reinterpretation in which the word in question is reconstrued in accordance with the semantics of the construction and the

semantic constraints that the construction imposes upon words that appear in it. As Michaelis [2004: 49] points out, coercion serves as a sort of conceptual resolution to semantic conflicts:

Grammatical constructions refer in the same way that words do: they denote types—among them classes of entities and events. Accordingly, coercion is not merely the resolution of a semantic conflict but it is instead the resolution of conflict between constructional and lexical denotata.

More specifically, the conflict is resolved in accordance with what Michaelis [2003: 10, 2004: 51] calls the Override Principle which states that “if a lexical item is semantically incompatible with its syntactic context, the meaning of the lexical item conforms to the meaning of the structure in which it is embedded”. The syntactic context semantically overrides the lexical item, coercing it into becoming semantically compatible with the construction in which it occurs. Instances of constructional-lexical coercion are often interesting in that identifying the loci and types of coercion can reveal details of the construal operations that are at play in a given construction in general.

5.2. Construal and Coercion Patterns in the English Progressive Construction

A verb that is incompatible with the English progressive construction is one that does not display the semantic features that characterize the progressive construction; that is, it is a verb that does not conventionally express durativity and dynamicity, and, consequently, the aspectual frame does not readily apply.

We saw that in example (3) in which *knock*, *jump* and *die* were changed from expressing punctual situations into expressing temporally extended, or durative, ones via the English progressive construction. This semantic conversion is quite clearly a case of coercion of the semantics of the verbs so they fit into the semantics of the progressive construction.

5.2.1. Verbs of Punctuality

The type of situation that is perhaps the most obviously incompatible with the English progressive construction is the punctual situation, or, in Talmy’s [2000a:63] terminology, the one-way situation—that is, a temporally non-extended situation. Despite the semantic incompatibility, verbs that conventionally refer to one-way situations do appear in the progressive construction and undergo coercion as seen in (3) above and (4) below:

- (4) a. The edges of her mouth were flickering, as if miniature hearts beat there.
(BNC C86 4288).
- b. She had called up the hall: "Yours ears are flapping, Mr O'Brien!" (BNC GVT 2017).
- c. The next moment I was on the floor and one was kicking me and the other was hitting me in the face. (BNC CS4 1338).

In (4a), the verb *flicker* appears in the progressive construction, and it typically refers to either a brief flash of light that lasts only for a moment or a brief and sudden small movement. This is not a type of temporally extended event. Nor is the situation expressed by *flap*, which, when not in the progressive construction, predicates a quick vertical or horizontal movement. Likewise, *kick* and *hit* typically refer to abrupt striking movements. Compare the examples in (4) to *The edges of her mouth flickered, as if miniature hearts beat there; She had called up the hall: Yours ears flapped, Mr O'Brien!*; and *The next moment I was on the floor and one kicked me and the other hit me in the face*, in which the progressive has been substituted with the simple past. The most likely readings of these are that the edges of her mouth flickered once, that Mr O'Brien's ears flapped once, and the the narrator of was kicked once and hit once in the face, because the simple past tense does not, unlike the progressive construction, have any construal operations of constitution/gestalt associated with it through convention. In contrast (4) expresses a series of flickers, several flaps of Mr O'Brien's ears, and several kicks to the narrator's body and hits to his face. As with (3a) and (3c), the punctual events have been iterated into series of identical processes such that the iterative series themselves are construed as main processes. The iterative series is temporally extended and displays durativity, making it compatible with the aspectual frame.

In Talmy's [2000a: 63] system of patterns of distribution, there are two types of one-way situation: the resettable one and the non-resettable one; the former is one that returns to its original state and the latter is one that cannot be reset to its original state. Croft [MS §2] makes a similar distinction between reversibility and irreversibility. The examples in (3a), (3c) and (4) are instances of coercion of a resettable punctual verb appearing in the progressive construction, while (3b) and the following examples in (5) are instances of non-resettable, or irreversible, punctual verbs in the progressive construction:

- (5) a. She was breaking an egg into a curl of boiling, salty water—the top of the big coal range glowed under a copper saucepan. (BNC H7H 203).
- b. We were winning 3–0 when I woke up. (BNC J1G 407).
- c. So the day had come, and she was accepting it very calmly. (BNC H7P 1015).

The breaking of an egg is a punctual event which occurs when the shell is broken, and it is non-resettable in that when an egg is broken, it cannot be unbroken. Likewise, the winning of a game itself is punctual, as a game is only won at the very moment that it is finished, and the process of accepting something, while it may require a lot of preceding thought and consideration, is in itself punctual, I would say. In any case, winning a game and accepting something are both non-resettables since a game does not normally revert from being won to being in its original state from before it was over, and, although, one can change one's mind eventually, the resultant state of the process of accepting something is not identical to the initial state. In (3b), death itself is punctual (although, of course, there may be several states and events leading up to the moment of death) and it certainly is non-resettable. However, in (3b) and in (5), these otherwise non-resettable punctual event verbs appear in the progressive construction and are coerced into durative processes which are compatible with the aspectual frame.

Either type undergoes its own specific pattern of coercion into a durative event, resulting in slightly different construals.

When a resettable one-way verb appears in the progressive construction, it is coerced into an iterative situation which can then be imperfectly construed. This coercion process involves a number of construal operations of structural schematization within the sphere of constitution/gestalt. To describe these construal operations, it is necessary to draw on Talmy's [2000a: 47–86] categories of configurational structure. The one-way resettable process is replicated through the operation of multiplexing. On Talmy's [2000a: 48] definition, multiplexing is all that is required in order to create a iterative process from a one-way process, but I would argue that the perception of something as a multiplex gestalt itself also involves melding. The operation of multiplexing merely replicates the event into several identical ones, but it is the operation of melding that allows one to view all of these replicated events as one gestaltic process and not merely a number of identical but mutually discrete events. So, through multiplexing, the events of flickering, flapping, and kicking and hitting in (4) and jumping and knocking in (3a,c) are replicated into several identical instances of each event, and, though melding, each set of multiply replicated types of event is construed as a coherent chain, or series, of iterated events. It should be mentioned that iterative processes, while gestaltic, are *per se* less continuous than proper durative ones because there are still breaks between each of the replicated events. Nevertheless, the events are construed as forming a series, or chain, and are thus perceived as a unit which is discrete from its context, suggesting that state of dividedness is a continuum ranging from discreteness to continuity. So, through multiplexing and melding, an iterative multiplex event is construed which consists of a holistic and semi-continuous series of replicated resettable one-way events. In terms of degree of extension, the event is coerced from being a point into an extent, but whether it is construed as a bounded or unbounded in terms of telicity is, as such, irrelevant to the progressive construction because of the gapping of the INCEPTION and TERMINATION. Having been coerced into an extent, the iterated process can now be subjected to the construal operations associated with the progressive construction, since it is now durative enough for the aspectual frame to be applied such that a MIDDLE PHASE can be set up and profiled, constructing an unbounded and ongoing event.

With non-resettable one-way events, coercion also results in an extended process, but with some notable differences in gestaltic structure. An important difference is that the non-resettable one-way event, unlike the resettable one, is not replicated and iterated. Iteration is logically impossible, because iteration of an event presupposes that it returns to its original state so that it can be repeated. This is not possible with non-resettables since their resulting states are considered permanent. The coercion process involves an operation in which the events leading up to the one-way non-resettable itself are included into the event, extending it such that the original non-resettable one-way event is reconceptualized as the termination or completion of the extended event. The main coercive process is likely to be melding, such that the events leading up to the non-resettable one-way event and the event itself are melded into one continuous event whose resultant state equals the resultant state of the original one-way event. Unlike coercion of resettable one-way event verbs, non-resettables are coerced into fully continuous events with no perceivable breaks at all between them. While the iterated events discussed above is only somewhere in between composite and continuous, non-resettables are coerced into fully continuous ones. Whereas telicity was irrelevant in the type of coercion discussed above, a non-resettable one-way event is construed into what Talmy [2000a: 63] calls a gradient action which is durative and telic. The outcome of this sort of coercion is more specifically a bounded extent whose boundaries are specified by the

initial and the resultant states. More specifically, the original one-way non-resettable constitutes the endpoint of the event. For example, death, which is a punctual event, is, in (3b) expanded such the situations and states that Nicholas Ferrar goes through leading up to his death, are melded with the actual point of death into one continuous process in which the change of state that is death simply functions as the endpoint of the TERMINATION phase. Similar processes of expansion through melding apply to the events in (5). Having been coerced into an extended gradient action, the event can now be construed imperfectly through application of the aspectual frame and profiling of the MIDDLE PHASE. When construed imperfectly, the MIDDLE PHASE coincides with the events originally leading up to the one-way non-resettable event but the non-resettable event itself is not included which means that when such verbs appear in the progressive construction, the change to the resultant state is typically not in the situational focus, and it may indeed not even take place. For instance, in (3b), *was dying* does not express the actual moment of death, but rather some stage in the process leading up to the moment of death, and similarly in (4a), *was breaking* refers not just to the moment of breaking of the shell of the egg, but to the processes leading up to it (and, in this case, probably also the events after the breaking of the egg, as its contents spill into the boiling water). In (4b), *were winning* expresses, not the moment of victory, but some stage of the game in which the narrator's team were leading the game 3–0, leading up to the victory but not constituting it, and (4c) refers, probably not to the acceptance itself, but to the processing, thinking and considering that take place prior to the acceptance itself. Thus, in such cases, “the progressive form describes a runup process before the achievement of the change of state” Croft [MS §2.2.2].

These two types of coercion of non-durative verbs into durative ones further support the claim that the progressive construction is conventionally associated with construal operations of degree of extension and requiring the event in question to be an extent in order for it to be construed imperfectly. These construal operations of schematic configuration are thus associated with the progressive construction independently of the verbs it appears with; had these features been associated with the verbs and not the construction, the progressive construction would either not occur with punctual verbs in the first place or coercion would not take place at all.

5.2.2. *Verbs of Stativity*

According to Borg [1998: 96–7], relational verbs never appear in the progressive construction, while mental and sensory verbs sometimes do; this more or less represents the view of many grammarians of English. In their corpus-based description of English grammar, Biber and colleagues [1999: 471] present findings that seem to confirm these constraints. However, Biber and his coauthors also show that relational stative and stative-like verbs do appear in the progressive, as in the following *being*-examples in and the *having*-examples:

- (6) a. The Hon. Gentleman is being rather longwinded. (BNC HHV 9751).
 b. He's being most kind. (BNC GV2 3501).
 c. All right, so maybe she was being unreasonable. (BNC H7W 3659).
- (7) a. Someone who doesn't want a meal but just wants a drink but all the rest of the people are having a meal. (BNC F7A 981).
 b. We are having to fight hard, to save our hospitals. (BNC H4A 101).

- c. A platoon from B Company were having their own shooting competition with the Canadians and Germans. (BNC A77 1895).

Many linguists who take into account usage patterns in naturally occurring language are aware of this [Greenbaum and Quirk 1990: 55–56; Leech 1971: 22–29; Stefanowitsch and Gries 2004: 230–231], and they also make the observation that such verbs typically adopt a more dynamic meaning in the progressive construction, which means that coercion is involved. This type of coercion can be described quite simply: “The activity feature ‘wins out’ over the stative feature of the input lexical item” [Michaelis 2004: 75].

This is one of the reasons why the examples in (6) can be somewhat oxymoronically described as dynamic states. The activity feature of the progressive in all three examples in (6) adds a sense of, not only temporariness, to *BE*, but also a sense of the state in question essentially being the result of behavioral activity by the referent of the subject. Thus, the state of longwindedness in (6a) is temporary because it follows from the behavior of the subject as perceived by the speaker. Similarly, the kindness in (6b) is more of a description of the behavior of the referent of the subject in at the moment, and Polly’s state of being unreasonable³ can also be argued to follow from her behavior. Indeed, taking into account the co-text, one will typically find that the behavior itself is described, as is the case of the example in (6c), which is presented in a larger portion of textual context below:

- (8) "Not stopping at Ibiza must have helped," Polly said drily.

The lift of one dark brow told her he recognised the gibe. Turning his back on the receiver, he folded his arms and leaned against the chart table. "So, what did you think of the market?"

Relieved that he had decided not to respond to her deliberately provocative remark, Polly was, at the same time, irritated. All right, so maybe she was being unreasonable. But it just seemed that he held all the cards, he made all the decisions. That wasn't true either. She made a wry face. (BNC H7W 3659).

Prior to the sentence in (6c), the text describes Polly’s provocative behavior towards the other characters in the narrative and also her feeling irritated. So, the sentence in (6c) is as much a description of her interaction with the other characters and her feelings towards them as it is a description of a state that she is in.

Similarly, the instances of the progressive in (7) impose a much more dynamic construal upon *HAVE* than its typical semantics of state of possession. The situation of having a meal in (7a) can hardly be said to be a state at all, which also applies to the situation of having a shooting competition in (7c). Example (7b) is a bit different, because it involves the semi-modal construction [*HAVE* to V], which typically describes a state of necessity or obligation, depending on whether it is epistemic or deontic. It is interesting that the activity feature even wins out over the stative feature of semi-modals and actually modifies the modal meaning into being a necessity that applies at the very moment as the referents of the subject are actually engaged in fighting to save the hospitals.

³ Interestingly, the adjectives longwinded, kind, and unreasonable could be argued to express attributes which are themselves derived from patterns of behavior.

The result of the coercion in (6) and (7) is sometimes referred to as a temporary state, understood such that it is essentially a stative relation between the participants in the situation but not a permanent state. However, Michaelis [2003: 75] argues that temporary states “are in fact not states but homogenous activities”. A homogenous activity is a process which appears stative and steady as no change of state appears to be going on, but this apparent stativity is caused by equal strength in the energy input of the AGENT and the force relations among the participants in the situation. Stative verbs that appear in the progressive construction do not express states at all but are coerced into actually expressing processes that involve force dynamic tension, but may not display any perceptible internal changes of state.

Central to this type of construal is reinterpretation of the force dynamic relations otherwise involved in the state that is conventionally expressed by the verb in question, such that the otherwise stative relations among the participants are replaced by dynamic ones of energy input which do not cause changes of state, maybe because the participants are equally strong opposing forces which hold each other in place rather than causing changes in one another, because the AGENTIVE participant holds the other participants in place, or because our encyclopedic knowledge simply informs us that the situation in question is an activity although it appears to be a state, as is the case of activities like sleeping or holding one’s breath [Michaelis 2004: 75]. With this reinterpretation of force dynamics follows a reinterpretation of patterns of distribution in that the SITUATION is changed from a steady state into a durative atelic process, which is absent from Talmy’s [2000a: 63] system, but accounted for by Croft [MS §2] as an activity and by Bache and Davidsen-Nielsen [1997: 191–195] as a self-contained process. The terms ‘activity’, ‘self-contained process’, or ‘durative atelic process’ all refer to an extended dynamic situation which does not progress towards a point of completion but may at any time be terminated, and, upon termination, the participants will revert to their initial states, or enter states which are not natural or logical or necessary outcomes of the process in question. These coercion patterns of the progressive construction obviously adhere to Michaelis’ [2003: 10; 2004: 51] Override Principle. Michaelis [2004: 68] also proposes another principle in *Aktionsart* and aspectual coercion, which she calls *Aktionsart* Preservation which states that, “in an aspectual mapping, whether implicit or explicit, input and output types must share some portion of their respective causal and/or temporal representations”. *Aktionsart* Preservation is closely related to, and perhaps even derived from, the Override Principle.

Certainly, in relation to the progressive construction, it seems that the coercion patterns are the direct results of the semantics of the progressive construction overriding the *Aktionsart* semantics conventionally associated with the verb in question. The progressive construction imposes a constitution/gestalt construal of durativity upon the situation in question so that the aspectual frame can be applied and the middle phase selected; thus, the progressive construction, as mentioned above, comes with an actional, or *Aktionsart*, specification of durativity. When punctual verbs appear in the progressive construction, they are coerced into different kinds of durative ones such that the durativity is preserved. Thus the progressive construction preserves its most central *Aktionsart* by overriding the *Aktionsart* semantics of the main verb.

CONCLUDING REMARKS

The main purpose of the present discussion draws in part on the basic tenet of construction grammar which holds that constructions are semiotic units that combine form and content, or meaning or function, and in part on the principle from general cognitive linguistics that linguistic meaning is a matter of construal, and involves mental processes, which apply not only in meaning constructing but also in general human cognition.

There is a certain logic, I think, to the combination of these two tenets of language and cognition, and its locus is the principle of the syntax-lexicon continuum. If constructional and lexical units are essentially semiotic units whose only main difference is that of internal complexity, then constructional meaning should be subject to the same meaning constructing processes and principles as lexical and morphological meaning. Therefore, it should be possible to describe constructional content in terms of the same construal operations that apply to lexical and morphological meaning.

I have attempted to provide an admittedly tentative, and non-exhaustive account of the possible meaning constructing processes of the English progressive construction, and, drawing on Croft and Wood's [2000, Croft and Cruse 2004] model of construal operations, I have suggested a number of construal processes that are likely to be part of the meaning constructing of the progressive construction. Dividing the semantic content of the progressive construction into three major components (the IMPERFECTIVE aspect, the SITUATION itself and TENSE), I accounted for the construal operations involved in each of these components. The component of IMPERFECTIVITY, that is the conception of the situation as an ongoing one, draws on a number of construals from the realm of attention/salience, the central one being the profiling of the MIDDLE PHASE of the aspectual frame while gapping the INCEPTIVE and TERMINATIVE phases by leaving them out of the situational focus. This is a relatively simple operation and most likely a central one in general human cognition and perception, which has, in different terminologies, been described extensively in the literature on aspect. The progressive construction also imposes a number of construals, primarily ones of constitution/gestalt upon the SITUATION itself. Firstly, the SITUATION is construed as unbounded by virtue of the inceptive and terminative phases being gapped. Secondly, the SITUATION is construed as a durative one displaying a high degree of extension; otherwise the aspectual frame with the MIDDLE PHASE profiled cannot be applied. Thirdly, while the exact nature of the force dynamics of the SITUATION is unconstrained, there is some sort of AGENTIVE role involved which provides some type of energy input that causes the situation to be a dynamic one that unfolds over time and can be scanned sequentially. Consequently, another construal operation of constitution/gestalt that applies is the specification, within the system of pattern of distribution, of the situation as a non-stative one. The discussion of coercion of verbs appearing in instances of the progressive construction, but which do not readily match the constructional semantics seems to support the idea that at least those five constitution/gestalt construals are conventionally associated with the progressive construction. Finally, although this has been presented as a minor point, TENSE is relevant to the progressive construction inasmuch as tensed instances of the progressive construction involved temporal deixis, which falls under the realm of construal operations of perspective/situatedness. In this respect, I mentioned the possibility of a temporal frame that

structures our general perception of time, and that tense might involve the profiling of parts of that frame.

The main premise that constructional meaning, like other linguistic meaning, is a matter of construal and can be accounted for in terms of construal operations, such as those in the model proposed by Croft and Wood (2000), is, I would argue, or should be considered, an important principle in those branches of construction grammar that seek to relate constructional form and meaning to human cognition.

Chapter 74

THE PRONOUN *It*: A STUDY IN COGNITIVE GRAMMAR

Zeki Hamawand

University of Kirkuk, Iraq

ABSTRACT

This paper explores two fundamental tenets of Cognitive Grammar (CG) with reference to the meaning of the English pronoun *it*. One tenet is that all linguistic elements posited in language have conceptual (semantic) import. On the basis of this tenet, I argue that the pronoun *it* is meaningful and its multiple senses can be characterised in terms of a prototype: a central sense from which other senses are somehow derived. The other tenet is that the meaning of a construction, as reflected in its particular morphosyntactic organisation, evokes a particular construal (imagery) imposed on its content. On the basis of this tenet, I argue that a construction containing the pronoun *it* is motivated by the construal of scope: the array of conceptual content, narrow or broad, which the speaker chooses to characterise an expression. In a narrow scope which is represented by a non-extraposed construction, the speaker considers a minimal range of content in describing the situation. In a broad scope which is represented by an extraposed construction, the speaker considers a maximal range of content in describing the situation. The speaker's ability to construe a situation in a variety of ways is considered a key concept in CG.

Keywords: construal, impersonal, personal, prototype, scope, setting

1. INTRODUCTION

One of the features of English grammar pertains to the existence of grammatical morphemes. On the types of sentences in which such morphemes appear, grammarians of English seem to agree. On the interpretation of such morphemes, however, they tend to differ. A telling example of a grammatical morpheme, which poses a problem to grammarians, is the

pronoun *it*, which is used to replace a noun or noun phrase which refers to things other than people in the discourse. The pronoun *it* occurs in a considerably broad range of constructions.

As illustrated below¹:

- 1) a. The pencil is blunt. *It* needs sharpening.
 b. The house is new. *It* has a swimming pool.
 c. The company is recent. *It* makes software.
 d. The dolphin is small. *It* is only 4 feet long.
 e. She needs love. Nobody provides it.
 f. Justice is important. One must support it.
 g. Famine is dangerous. It results in deaths.
 h. He tries to go into the film business. It is no easy matter.
- 2) a. It is Sunday.
 b. It is cold.
- 3) a. It is convenient to do banking by phone. To do banking by phone is convenient.
 b. I like it when everyone attends the party.

The constructions cited above highlight some of the different uses of the pronoun *it* in English. The constructions under (1) represent the use of *it* as a personal pronoun, where *it* is assigned the task of referring. *Reference* is a relationship between two linguistic elements, in which one refers to the other and so provides the information necessary to interpret it. The constructions under (1a-d) include examples of concrete entities. In (1a), *it* refers back to a lifeless object represented by *pencil*. In (1b), *it* refers back to a place represented by *house*. In (1c), *it* refers to an organisation represented by *company*. In (1d), *it* refers to an animal represented by *dolphin*. The constructions under (1e-h) include examples of abstract entities. In (1e), *it* refers back to an emotion represented by *love*. In (1f), *it* refers back to a concept represented by *justice*. In (1g), *it* refers back to a condition represented by *famine*. In (1h) *it* refers back to a situation represented by a clause.

The constructions under (2) and (3) represent the use of *it* as an impersonal pronoun, where *it* is assigned the task of non-referring². *Non-reference* is a relationship between two linguistic elements, in which one does not refer to the other but still provides the information necessary to interpret it. The constructions under (2) are simple in structure. In (2a), *it* embraces time represented by *Sunday*. In (2b), *it* embraces weather represented by *cold*. In this function, *it* is referred to, Quirk et al. (1985:348-9), as *dummy*, a grammatical unit which has no meaning, but completes a sentence to make it grammatical.

The constructions under (3) are complex in structure. In (3a), *it* anticipates the subject represented by *to do banking by phone*. In this function, *it* is referred to, Quirk et al. [1985:1391], as *anticipatory*, a grammatical unit which anticipates something

¹As is clear, the purpose of this paper is to account within the framework of CG for the occurrences of the pronoun *it* in various construction types in English. Because of that, I will not address the relationship between *it* and other English pronominal elements such as *this* or *that*. For such information, the reader is referred to Strauss [2002].

²The non-referring *it* has been variously called by grammarians: preparatory *it* [Jespersen, 1970], provisional *it* [Kruisinga, 1932], and introductory *it* [Hornby, 1975].

which appears later in the same sentence. The subject takes the form of a *to*-infinitive complement clause. The complement clause could also be an *-ing* gerund as in *It is pleasant watching a landscape*, or a *that*-clause as in *It is probable that she will make a full recovery*. In the present analysis, the focus will be restricted to infinitival complement clauses. In (3b), *it* anticipates the object represented by *when everybody attends the party*.

The constructions under (3) display alternation between two types of constructions. In (3a), the subject of the main clause is simply understood as indefinite or non-specified. This construction is referred to as *non-extraposed*, a construction in which the complement clause appears in the normal clause-initial position before the main predicate, which is the usual position for subjects in English. In (3b), the subject position of the main clause is occupied by the pronoun *it*. This construction is referred to as *extraposed*, a construction in which the complement clause appears in final position after the main predicate, and the subject position of the construction is filled by the pronoun *it*. *It* anticipates a *to*-infinitive complement clause represented by *to do banking by phone*.

A look at the various uses of *it* in the above constructions raises three questions. Concerning the constructions under (1-3), the question is: is *it* meaningful, and if yes what accounts for the variety of meanings which it exhibits? In terms of the cognitive approach adopted here, I will show that *it* is meaningful and its multiplicity is ascribed to the notion of *polysemy*, the fact that a lexical item has many but related senses. Concerning the constructions under (2), the question is: does *it* represent anything in such expressions?

In terms of the cognitive approach adopted here, I will show that *it* functions as a *setting*, the expanse within which an activity takes place.

Concerning the constructions under (3), the question is: does *it* contribute to the construction in which it occurs, and if yes what accounts for the difference between the alternative constructions? In terms of the cognitive approach adopted here, I will show that the employment of *it* is attributed to the notion of *scope*, the array of conceptual content which the speaker chooses to characterise an expression. The goal is to show how the cognitive analysis provides linguists with the necessary tools to convincingly investigate grammatical morphemes.

To tackle the issue of the pronoun *it*, I will organise the paper as follows. In section 2, I will probe the first question, namely the polysemous characterisation of *it*, which is couched within the notion of *prototype*. In section 3, I will investigate the second question, namely the status of the impersonal *it*. In 3.1, I will look at some previous analyses that have been made by scholars concerning the question.

Depending on their nature, I will group the analyses into two types: syntactic and semantic. In 3.2, I will posit the cognitive analysis of *it*, introducing the notion of *profile* and applying it to example constructions. In section 4, I will examine the third question, namely the contribution of *it* when it occurs in extraposed constructions. In 4.1, I will survey some of the previous analyses that have been made by scholars regarding the question.

Depending on their nature, I will group the analyses into three types: stylistic, syntactic and functional. In 4.2, I will posit the cognitive analysis, introducing the notion of *scope* and applying it to example constructions. Section 5, I will summarise the results of the analysis.

2. POLYSEMOUS *IT*

CG, as represented by Langacker [1987, 1991a], is a linguistic theory which views language as part and parcel of cognition, and regards grammar as being inherently meaningful. It focuses on language as a cognitive entity, and aims to describe those aspects of cognitive processing which underlie the linguistic system. Grammar is thus considered symbolic in nature; it reduces to the structuring of conceptual content. Unlike other models of grammar which assume that language is detached from the world of thought, CG maintains that human thought and language are not two separate modules but are intimately interrelated. CG considers the speaker's ability to conceptualise a situation in a variety of ways, and takes into consideration the role of human experience in providing the basic meanings coded in natural language. Linguistic meaning does not reside in conceptual content alone, for speakers are able to construe the same content in alternate ways, resulting in substantially different meanings coded in different linguistic structures.

In CG, a linguistic expression is a symbolic assembly. It has two poles: a semantic pole, its meaning, and a phonological pole, its form. The semantics associated with a symbolic expression is linked to a particular mental experience termed a concept, which derives in turn from a percept. The phonology associated with a symbolic expression is its perceptible form, which can be spoken or written. The use of a symbolic expression then involves mapping between its meaning and its form. All elements provided by language are ascribed semantic values, which motivate their grammatical behaviour. A lexical item or a grammatical marker is often polysemous, having multiple senses. These senses form a complex category, a network of interrelated senses by extending from a central sense, termed the *prototype*. From the central sense, all the other senses can somehow be derived. The central sense is usually the most frequent sense and the first sense learned in the process of language acquisition. The other different senses are linked to the central sense via semantic extensions.

In accordance with the *prototype* theory³, I argue that the pronoun *it* is a symbolic unit, being meaningful in all its uses. It forms a category of senses which are semantically motivated. That is, the meaning of *it* can be characterised by a complex network of senses, extending from a prototype. The senses in the network are related to one another in two ways: schematicity marked by solid arrows and extension marked by dashed arrows. A is schematic for B, while B is an elaboration of A. The senses vary greatly in their degree of salience. The criteria for distinguishing the different senses of *it* can, I argue, be established in the idealised model of *concreteness*. This model is scalar in dimension in that the entity described falls into two classes: concrete, referring to something viewed as a material entity, and abstract, referring to something viewed as a non-material entity. A speaker's knowledge of the pronoun *it* therefore embraces the entire network.

Prototypically, the pronoun *it* is assigned the status of reference. In this role, *it* means 'referring back to an entity which has previously been mentioned in the discourse'. An entity is something that exists as a material object in the real world or a non-material concept in the imagined world. In this use, *it* is parallel with other 3rd person pronouns. Relative to its nature, the entity is of the following types:

³For more discussions of the prototype theory, see Rosch [1978], Lakoff [1987] and Taylor [1989].

- a. In some cases, the entity is concrete. In *Have you seen my book? Yes, it is on the table*, *it* refers back to a lifeless object represented by *book*. This sense can be semantically extended to anaphoric senses for other kinds of antecedents. In *Have you been to London? Yes, it was very crowded*, *it* refers back to a place represented by *London*. In *Many people watch the BBC. It started broadcasting in 1937*, *it* refers to an organisation. In *The bear approached Patrick. It has thick fur*, *it* refers back to an animal, especially when its gender is not known. Some people use *it* to refer to babies in this way, as in *The mother feeds the baby. The father bathes it*⁴.
- b. In other cases the entity is abstract. In *Everyone is asking for love. Few seem able to provide it*, *it* refers back to an emotion. In *Truth is important. One must always speak it*, *it* refers back to a concept. In *Thousands live in poverty. We must combat it*, *it* refers back to a condition or state. In *I am trying to get a taxi. You won't find it easy*, *it* refers back to an entire situation, in which an event coded as a clause is reified as a kind of abstract thing.
- c. In rare cases, *it* is cataphoric. In this role, *it* means 'referring forward to an entity which comes later in the discourse'. This is a case of right-dislocation, moving an element to the end of a sentence. It is found mainly in spoken language. It is used to add clarification to a noun phrase. The entity could be concrete, as in *I liked it, the food*. It could be abstract, as in *I enjoyed it, dancing the tango*.

Peripherally, the pronoun *it* is assigned the status of non-reference. In this role, *it* means 'profiling a setting within which an activity is introduced'. A setting represents the region within which an event unfolds or a situation obtains. It is an expanse within which an activity is introduced or a context within which it emerges. Depending on the nature of the complement, the setting is of two types:

- a. In some instances, the setting is concrete. In *It is five o'clock* or *It is Tuesday*, *it* profiles a temporal setting, a location in time within which an action occurs. Recall that English allows sentences like *Monday witnessed a historic development*, in which *Monday* profiles a temporal setting within which the action of development is conceptualised to occur. Normally, one cannot conceptualise an event without connecting it with the time in which it occurs. In *It is freezing*, *it* profiles a spatial setting, a location in space represented by the environment, within which the action of freezing takes place. Recall that English allows sentences like *Chicago is freezing*. Naturally, one cannot conceptualise a meteorological event without connecting it with the environment causing it⁵.

⁴For a detailed treatment of English anaphora from a CG perspective, the reader is referred to van Hoek [1997].

⁵Some grammarians like Zandvoort [1962: 134], Visser [1963: 34], Onions [1932: 142] and Quirk et al [1985: 349] treat anticipatory *it* as a special kind of referential *it*, referring forward to the embedded clause. To defend the view that impersonal and extraposed *it* is non-referential, Jugnet et al [2006] provide two arguments. The first argument is based on a property of without adjuncts. In impersonal constructions, the presence of *it* in a subject position following *without* is optional, as in *It never thunders here without Ø/it raining for days afterwards*. There is no clear difference between the two variants, so it is hard to see if *it* contributes a referential meaning. This is unlike a normal sentence where the subject position should be empty due to coreferentiality with the main clause subject, as in *He never laughs without *him crying right afterwards*. Likewise, *it* cannot alternate with a phrase having a similar reference, as in **In Paris is raining*. The same argument applies to *it* in extraposed constructions, as in *If you are in fact forcing the issue, it is very difficult*.

- b. In further instances, the setting is abstract. In *It is tragic to hear the news of a plane crash*, it is used as an anticipatory subject, and so the construction is referred to as a *setting-subject construction*. It profiles an abstract setting within which a situation represented by a complement clause takes place. Moreover, it codes the general circumstances that surround the occurrence of the complement clause. In *I would hate it if they said so*, it is used as an anticipatory object, and so the construction is referred to as a *setting-object construction*. It profiles an abstract setting within which a situation represented by a complement clause takes place. Moreover, the presence of *it* serves to iconically distance the content of the complement clause from the main clause subject⁶.

For convenience, I will summarise in Figure 1 below the semantic structure of the impersonal pronoun *it*. Let us summarise the main thrust of the argument. Prototypically, *it* is assigned the status of referring. *It* refers back to a concrete entity. Peripherally, *it* is assigned the status of non-referring. *It* serves as setting hosting an occurrence. The source of the non-referring *it* is, I argue, from its use as a referring pronoun, which represents a natural extension.

Figure 1. The semantic network of the impersonal pronoun *it*.

to do so without it seeming that you are doing so. The second argument is on coordination. In extraposing a coordination of clauses which trigger plural agreement if they are in subject position, it is impossible to have both in subject position in place of it, as in *It was*/**Both* were surprising to me that she suggested buying steak and that he agreed.

⁶ In this use, the presence of the pronoun *it* is explained by the principle of conceptual distance. As Haiman [1983:782] explains, “The linguistic distance between expressions corresponds to the conceptual distance between them”. On the basis of this, it is used to iconically distance the content of the complement clause from the main clause subject or from the attitude expressed by the main clause verb. As noticed by Smith [2002: 97-8], the conceptual distancing can be motivated for a variety of reasons. Most often, it occurs when the complement clause follows negative-implying verbs as in the example given above. However, it can also occur if the complement clause follows positive verbs, as in *I like it when they win*. In such cases, it helps the speaker to view the desirable complement content from a distance so that its entire import can be properly appreciated.

It is caused by a metonymic operation by which *it* ceases to refer back to an entity and instead comes to profile a setting of some sort within which an occurrence is construed to happen. The use of the non-referring *it* represents then an instance of setting-subject constructions. Consequently, such constructions are classified as setting-subject constructions, and an important part of their analysis thus consists in defining the specific nature of the setting *it* profiles. Such constructions in which the focal status is conferred on the setting are referred to as *setting-subject constructions*. Overall, the pronoun *it* represents an important test case for the claim that grammar comprises only meaningful elements.

3. IMPERSONAL *IT*

In the semantic network of the pronoun *it*, one important example that has been demonstrated pertained to its occurrence in impersonal constructions. In describing a situation, the speaker has, relative to the demands of discourse, the ability to single out different participants for focus. The question posed then is: what does *it* exactly represent in such constructions? In this regard, the status of impersonal *it* has been repeatedly addressed in the literature. Different views have been expressed. Due to the absence of agreement, I feel that a fresh look at the problem under investigation from a cognitive perspective is necessary. The aim is to see if a cognitive discussion of the problem has the potential of shedding more light on the question. To answer the question, I will pursue two steps. First, I will survey the previous analyses and see how they treat *it*. Second, I will identify the type of construal, posited by the present analysis, which *it* represents.

3.1. Previous Analyses

Previous analyses of the impersonal *it* proceed in two different trends. The first is syntactic and represents Traditional Grammar and Transformational Grammar. The second is semantic and represents Functional Grammar. Each analysis is a reflection of the underlying assumptions of the theory it adopts. In 3.1.1, I will provide a brief overview of the syntactic analyses. In 3.1.2, I will present a brief overview of the semantic analyses. At the end, I will point out the difficulties of each analysis. The purpose behind discussing previous analyses is not to criticise them but to find out if they are relevant to the present analysis or to see if the present analysis can build on any of their assumptions.

3.1.1. Syntactic Analyses

Under traditional analysis, Jespersen [1970:144] describes the anticipatory *it* as meaningless, where *it* occupies subject position and anticipates the subject. He writes: “*It* stands as a preliminary representative of a longish group of words which follows later because its placement here would make the sentence-structure cumbersome or top-heavy”. In this function, *it* serves to herald a deferred subject, hence it is often referred to as a *dummy* subject, as in *It is lovely to walk/walking along the beach*. The insertion of *it* in the vacant place of a postponed clause is the result of a grammatical device to make the sentence conform to the norm, i.e., the structural need for a surface subject. According to Jespersen, as

quoted by Morgan [1968:86], it is a condition of well-formedness for declarative sentences in English that they have an overt subject in the normal position, and that where this condition is not met, for whatever reason, an *it* is inserted. Sentences with anticipatory *it* must be distinguished from sentences where *it* is a pronoun and acts as a replacement for an inanimate object, as in *I don't like the look of this car, but I will buy it*.

Under transformational analysis, Rosenbaum [1967] considers anticipatory *it* the head noun in the deep structure, which gets deleted when the phrase of which it is the head is not extraposed to the end of the sentence. *It* is the head noun of the noun phrase containing the extraposed construction. According to Morgan [1968:84], this is unjustifiable, since head nouns, like pronouns, must have index of intended referent. So, he changes Rosenbaum's proposal and says that *it* is only an empty morpheme, with no index for referent, which is merely left as a marker when extraposition occurs. In Relational Grammar, Perlmutter [1983:160-2] accounts for the presence of *it* in the following way: when no other nominal is the final subject of a clause, a dummy element must be inserted into the clause as a final subject. The reason is to keep the finite verb from appearing in initial position. When the subject slot in an impersonal structure is vacant, the dummy appears to fill it. Consequently, the dummy determines surface agreement.

Haegeman [1991:53-5] and Haegeman and Guéron [1999:42] refer to *it* as an *expletive* pronoun, which is required to fill a gap following the application of the meaning-preserving transformation of extraposition. *It* turns up in the subject position of a sentence, i.e., the noun phrase position for which the verb does not subcategorise, and to which the verb does not assign a thematic role. In the semantically equivalent pair of sentences *To see him around surprises me* and *It surprises me to see him around*, *it* plays no role in the semantic make-up of the extraposed one; its presence being required for structural reasons only. *It* is considered a non-referential element because it does not refer to an entity, a person or an object. Unlike a noun phrase subject which receives a thematic role, *it* cannot be questioned, as in **What surprises me to see him around? It* has neither a thematic role nor a semantic content; therefore it cannot be questioned or otherwise replaced. *It* functions as a grammatical subject of a sentence whose real subject is a deferred noun phrase.

Seppänen et al. [1990: 756-7] and Seppänen [2002] attach to anticipatory *it* the function of a meaningless dummy subject. To back up *it*'s meaningless status, they provide two pieces of evidence. First, impersonal *it* and anticipatory *it* have no equivalent in other languages at all. Second, in coordinated structures the second *it* can be reduced, as in *It is snowing, and (it is) rather difficult to go on driving*. Likewise, Seppänen et al. [1990: 753-4] identify anticipatory *it* with non-referring *it*. The only difference is that anticipatory *it* is used with a notional subject. To reveal *it*'s lack of referential force, they propose two pieces of evidence. First, if *it* were referential it should alternate with the stressed pronoun that as in *It/*That won't be easy to get taxi to the station*. Second, *it* cannot replace plural *they* when the latter refers to a sentential antecedent, as in *To speak French and to understand mathematics are both important, but they/*it are not the most important things in the world*. These views can easily be dismissed as the evidence presented does not seem conclusive. For detailed counter-evidence against them, see Kaltenböck [2003: 235-55]⁷.

⁷ Some grammarians like Kruisinga [1932:715], Visser [1963: 36], Biber et al [1999: 332] also consider the impersonal *it* meaningless.

For syntactic analyses it seems that the answer to the question concerning the meaningfulness of *it* is clearly *No*. Syntactic analyses consider *it* a meaningless element inserted obligatorily in certain positions in certain structures to fill a place that would otherwise be unfilled. Traditionalists view *it* as a mere syntactic place holder whose only function is to satisfy the structural need for a surface subject in English. Transformationalists view *it* as a mere slot-filler of the otherwise unfilled subject position and as a pronoun without any semantic contribution to the construction. In the literature, *it*'s presumed lack of meaning explains the label of *dummy* or *pleonastic* given to the pronoun. Sometimes, *it* is referred to as the anticipatory subject or the grammatical subject. The clause which is related to *it* is sometimes referred to as the logical subject or the real subject.

3.1.2. Semantic Analyses

Under semantic analysis, the fact that impersonal *it* cannot be substituted does not necessarily indicate that it is meaningless. Semantic investigations of impersonal constructions have attempted to show that *it* is a real subject, and provides a semantic import to the construction in which it occurs. In disagreement with those treatments which deny any value to *it*, Bolinger, in a pioneering work on *it* (1977a, 1977b), contends that there is more to the meaning of *it* than a mere non-referring function. Bolinger shows that in certain cases, the non-extraposed equivalent of the impersonal construction is ungrammatical; therefore, *it* must have some semantic import beyond its cataphoric value. As evidence, he presents an example like *It's pleasant in California* vs. **In California is pleasant*. If the semantic function of *it* were merely to cataphorically refer to the location *in California*, one would expect that location to be able to occur as subject in the non-extraposed equivalent. The example cited above shows that it is not the case, and that *it* must be adding its own semantic import.

Bolinger (1977a:84) considers *it* a morpheme with its own lexical content. He analyses *it* as "a nominal with the greatest possible generality of meaning". He attaches to *it* the property of ambience, which means that "*it* has as its referent precisely the 'environment' that is central to the whole idea". Bolinger (1977a:77) calls *it* "ambient". The real importance of *it* is the coding of some kind of general circumstances surrounding the event presented in the expression. Bolinger argues that all the uses of *it* stem from this common semantic base. As evidence, a sentence containing *it* can be specified by the addition of a redundant adverbial, as in *It is cold outside*. Likewise, a sentence containing *it*, (ibid: 80), cannot be questioned by interrogative pronouns as in **what is cold*.

In Chafe's [1970:101-2] treatment, *it* is commonly viewed as serving the function of pointing forward to an extraposed clause. In this way, *it* is thus considered not to be completely devoid of meaning. The most obvious characteristic of the impersonal pronoun *it* is its close relationship with the clause content. Chafe focuses on that relationship and argues that the overall import of *it* is cataphoric. *It*'s importance pertains primarily to the speaker's sense of how important the referent is going to be in the upcoming discourse. In this sense, *it* cataphorically announces the content expressed in the complement clause in spite of the fact that *it* does not have any normal meaning. For example, in a sentence such as *It is useless to talk to him*, the impersonal *it* cataphorically serves to announce the complement content *to talk to him*. In essence, *it* is deemed a herald that something important is soon going to happen.

In Deane's [1992:158-9] view, *it* is used to refer back to a previous clause, as in *Did John come? I don't believe it*. On the basis of this anaphoric use, Deane analyses the expletive *it* of

extraposition as a pronoun whose antecedent is the extraposed clause. Consequently, *it* is a genuine subject and provides an argument for the clause to be predicated of. If we exclude the extraposed clause, a sentence containing expletive *it* has exactly the same basic structure as a sentence with a clausal subject. The extraposed clause is the only unusual aspect. It appears to be loosely adjoined to the rest of the construction even though it bears a special relationship with the expletive pronoun. The relationship between the pronoun and the extraposed clause can be described in terms of mutual linkage. The expletive pronoun is linked to the extraposed clause through reference. The linkage between them is caused by the fact that they cannot occur on their own.

Following Bolinger [1977a], Kaltenböck [2003:235-255] considers the anticipatory *it* a definite nominal which retains some of the referential force of the referring *it*. In this way, it allows *it* to establish a referential link with a clausal constituent in the immediate context. As such, anticipatory *it* takes an intermediate position between non-referring and referring *it*. *It* is related to the other types of *it* by a scale of gradience which specifies its scope of reference. Kaltenböck's view differs sharply from a formalist approach which describes *it* as meaningless. Unlike the formalist practice of verifying hypotheses about the classification of linguistic items by means of grammaticality judgements of isolated sentences, Kaltenböck's approach takes into account corpus data of actually occurring instances of anticipatory *it*. This is so because in the formalist approach the meaning of a particular form resides in the speaker's competence, whereas in Kaltenböck's functionalist approach it is also the result of interaction with contextual factors.

For semantic analyses, *it* has meaning of its own, and thereby provides a semantic contribution to the construction in which it occurs. Bolinger argues that *it* is meaningful, with the whole ambience of the situation as its referent. For the purposes of the present study, Bolinger's analysis of *it* is quite relevant as it attaches a specific meaning to it. The uses of *it*, however, have been limited to simple constructions, e.g., weather. On this basis, the meaning *it* has cannot be generalised unless it is applied to complex constructions containing complement clauses, which the present study attempts to explore. By contrast, Chafe and Deane argue that *it* is a syntactic entity when it points to a clause and a semantic entity when it points to a proposition. As is clear, such treatments of *it* can be considered half-way between syntactic and semantic analyses. For the purposes of the present study, such analyses are not quite relevant as they do not give *it* any explicit or precise meaning.

3.2. Cognitive Analysis

Under the cognitive analysis, the syntactic hypothesis that the expletive *it* is motivated to fill in a subject position is just the structural part of the story. This is so because English generally requires overt subjects. The hypothesis that the *it*-construction is the result of movement is questionable. There is no evidence from history showing that the *it*-construction had at an earlier stage a non-extraposed counterpart. In tracing the history of the 'quasi-impersonal subject' *it*, Kim [1999:338] found that a *that*-clause was always post-verbal. Thus, it cannot be claimed that any movement of a *that*-clause has occurred over time. The diachronically constant post-verbal position of the *that*-clause discourages one from assuming an extraposition transformation synchronically. Rather, the expletive *it* began to be used only to fill in the subject position as the language turned from a status which does not require a

prototypical subject to that which requires *it*. However, the semantic hypothesis that *it* is not truly devoid of meaning and that *it* adds a semantic substance to the construction in which it occurs is accepted in the present analysis.

The present analysis embraces Bolinger's thesis, but goes a step further and provides an analysis of *it* couched within the theory of CG. In terms of CG, *it* has a semantic import. *It* encodes distinct uses, which are a response to the communicative needs of the discourse. The cognitive approach adopted here is in conflict with the other ones for some good reasons. The traditional analysis considers *it* as meaningless; *it* anticipates the real subject which comes later in the discourse. The transformational analysis contends that *it* is incapable of encoding any meaning; *it* is merely the product of transformation. Even though *it* is considered meaningless, some transformationalists, notably Radford [2004:230], recognise that it must be marked for person and number, so it is not entirely a cipher. The functional analysis attaches only one single meaning, that of ambience, to the morpheme. In what follows, I will introduce the notion posited by CG, and demonstrate how it can be fruitfully applied to tackle the issue of the impersonal *it*.

3.2.1. Profile

In CG, a crucial aspect of meaning is the speaker's ability to construe a situation in more than one way. The speaker's attitude in shaping his or her utterances is incorporated in the notion of *construal*. Langacker [1987:487-8] defines *it* as "the relationship between a speaker (or hearer) and a situation that he conceptualises and portrays". Construal is a mental operation that helps the speaker select the appropriate structural possibility among various alternatives to match with his/her conceptualisation. The ability of the speaker to make alternative conceptual choices results in different morphosyntactic manifestations. As Langacker [1991b:ix] points out: "There are many different ways to construe a given body of content, and each construal represents a distinct meaning; this is my intent in saying that an expression imposes a particular image on the content it evokes". Grammar provides the speaker with conventional structures to draw on in mapping his conceptualisations onto language. These grammatical structures, as Langacker [1987:98] stresses, are the syntactic realisations of the speaker's conceptualisation.

One relevant dimension of construal is the conceptualiser's ability to impose a profile on a base, which directs the semantic value of a linguistic expression. This is referred to as *profiling* by Langacker [1988:68-9]. In his model of grammar, the semantic pole of an expression always has a certain *base*, defined as the array of conceptual content it evokes and draws upon as the basis for its meaning. Within the base, a particular entity is selected for designation. This designatum is referred to as *profile*, defined as the substructure within the base of an expression which functions as a focal point and receives the highest degree of prominence. Linguistically, such a profiled substructure is most likely placed in an important position, which is subject position. Semantically, the profiled substructure is held responsible for triggering an action, making an assessment or inducing an experience expressed by the expression.

Another relevant dimension of construal is the conceptualiser's ability to confer subject or object status on a substructure within a base. This is referred to as *participant choice* by Langacker [1991a:330-5]. The one that stands out as the primary figure within the expression is referred to as the *trajector*, which is often associated with the function subject. The other that acts as the secondary figure is called the *landmark*, which is often associated with the

function object. The notions of trajector and landmark are very close to Talmy's notions of *figure* and *ground*. Langacker [1987:120] writes: "the figure within a scene is a substructure perceived as 'standing out' from the remainder (the ground) and accorded special prominence as the pivotal entity around which the scene is organised and for which it provides a setting. Figure/ground organisation is not in general automatically determined for a given scene; it is normally possible to structure the same scene with alternate choices of figure".

To make all this clear, let us consider Langacker's [1991a:295-7] examples, where the action chain is realised linguistically differently, and where the speaker chooses to profile different segments of it. In a three-element action chain like *Floyd broke the glass with a hammer*, the entirety of the action chain is in profile; the agent *Floyd* is coded as subject, the patient *the glass* as object, and *a hammer* as instrument. In a two-element action chain like *The hammer broke the glass*, the agent is left unprofiled, while the rest of the chain is in profile; the instrument is coded as subject and the patient as object. In a single-element action chain like *The glass broke*, the agent and the instrument are left unprofiled, while the patient alone is in profile, and hence coded as subject. Profiling can, however, fall on other aspects of an expression. [Langacker:in press] In *Florida experiences a lot of hurricanes*, the spatial setting designated by *Florida* is in profile and hence coded as subject. In *The last few decades have witnessed amazing scientific progress*, the temporal setting designated by *decades* is in profile and hence coded as subject.

The consideration of these examples reveals some important cognitive principles. First, profiling is not an either/or matter. The particular profile imposed on a base is a consequence of the way the conceptualiser construes the scene, and not an inherent property of that scene. Different linguistic expressions can have the same base, and only be different due to the nature of their profile. Second, the recognition of an entity as subject or object is independent of its thematic role. Structural assignment is treated as a matter of clausal prominence, irrespective of any thematic role. The particular realisation of a linguistic expression then represents the conceptualiser's choice to express what is most important depending on its communicative needs. This is done through the process of assigning prominence to certain elements within the expression. Third, in describing a situation the speaker can resort to a non-delimited range of considerations. In what follows, I apply these notions to the description of the impersonal *it*.

3.2.2. Application

To see how this works, let us analyse some examples. In the construction *It is five o'clock*, *It is freezing*, or *It is getting rather late*, *it* profiles a concrete setting within which an activity takes place. *It* profiles what Langacker [1999:357-60] calls a *presentational frame*, in which a situation of some sort is introduced. *It* pertains to the presentation of the situation rather than being part of it, and shows how important the situation introduced in the upcoming discourse is going to be. In fact, there is a kind of container-content relationship between *it* and the situation, as Smith [2002:77] also found in the case of German *es*. In such a relationship, *it* serves as a container, and the temporal or spatial event as its content. In the examples cited so far, *it* is assigned a non-participant status in the profiled event, being nothing more than a frame with a presentational function. In such examples, the frame that *it* designates is selected for primary focal prominence because *it* serves to introduce the event and because the construction lacks a suitable participant to put in focus.

In the construction *It is tragic to hear the news of a plane crash*, *it* profiles an abstract setting within which a situation represented by a complement clause takes place. *It* profiles a setting or a host, in which an event is construed to happen. *It* serves as a setting-subject marker, identifiable as the immediate scope of the expression. The immediate scope is the general locus of viewing attention with respect to which a situation is interpreted. The immediate scope represents the general focus of attention and contains the event that is in profile. In this use, the pronoun *it* profiles what Langacker (in press) calls a *field* or *scope of awareness*, everything evoked in assessing an issue at hand. *It* represents a case of non-delimitation or vagueness in its reference. In this use, *its* crucial import is to code some kind of general circumstances surrounding the event presented in the complement clause. In the example cited above, *it* profiles a setting within which the event of a plane crash takes place, and draws attention to the general circumstances surrounding it. In this example, the speaker's emotion is inspired mainly by the crash of the plane, and might include other circumstances surrounding it, e.g., loss of life, shock that strikes the families, shake of confidence in travelling by air, harm inflicted on the reputation of the airlines, etc.

4. EXTRAPOSITION *IT*

In the semantic network of the pronoun *it*, one important example that has been demonstrated pertained to its occurrence in clausal complementation. In response to the needs of communication, the speaker can describe a situation in different conceptual ways and, making use of the linguistic resources, map them onto different syntactic forms. In impersonal constructions containing complement clauses, the speaker's conceptualisations take two forms: non-extraposed and extraposed constructions. In the former, the complement clause appears in initial position before the main predicate. In the latter, the complement clause appears in final position after the main predicate, and the subject position is filled by the pronoun *it*. The question posed then is: what is the difference between the two constructions? To answer the question, I will set two tasks to achieve. First, I will pinpoint the factors, suggested by the previous accounts, which affect the use of either construction. Second, I will specify the type of construal, suggested by the present account, which is imposed on the scene of either construction and triggers its syntactic form⁸.

4.1. Previous Accounts

Previous accounts suggest three types of distinction between non-extraposed and extraposed constructions. One type of distinction relates to style. In 4.1.1, I will devote the discussion to stylistic distinction. Another relates to syntax. In 4.1.2, I will dedicate the discussion to syntactic distinction. A further one relates to function. In 4.1.3, I will present the functional distinction. At the end, I will point out the difficulties of each analysis. Due to the disagreement among grammarians concerning the distinction between the two types of construction, a new cognitive analysis seems essential. The new analysis will take into

⁸ Some grammarians like Jespersen [1970], Biber et al [1999: 660] and Huddleston and Pullum [2002: 1481-2] consider the use of anticipatory *it* in extraposed constructions meaningless.

consideration the use of the constructions in context. The aim is to show that *it* is not randomly chosen from the lexicon, but rather employed relative to the way the speaker construes a situation.

4.1.1. Stylistic Distinction

With respect to style, two factors affect the structural alternation. One factor is informal style, which is suitable for ordinary situations. For extraposed complement constructions, the disparity, according to Mair [1990:40], is slightly in favour of this style, as in *It is advisable to disconnect the computer before you open it*. The other is formal style, which is suitable for official situations. For non-extraposed complement constructions, the disparity is highly in favour of this style, as in *To disconnect the computer before you open it is advisable*. From this, it follows that a non-extraposed complement construction has a formal flavour.

In the spirit of the times, Langacker [1974:653] claimed that extraposition is stylistic in character. It facilitates the production and comprehension of sentences by allowing the displacement of heavy constituents to final position, where they can be handled without disrupting the processing of the remainder of the sentence. In brief, in the absence of considerations mentioned in the following sections, extraposed complement constructions are clearly the more common and the more natural, whereas non-extraposed complement constructions are rather formal and often awkward. Although the extraposed construction is much more frequent, Huddleston [1988:451] describes the extraposed construction as being derived transformationally from the non-extraposed one⁹.

4.1.2. Syntactic Distinction

With reference to syntax, two factors govern the structural alternation. One factor is syntactic complexity, as mentioned by Wasow and Arnold [2003:119]. According to this factor, the employment of extraposition moves longer clauses to the end of a sentence to facilitate production. In *To learn that his new home is furnished is a relief*, the subject of the sentence is the clause *to learn that his new home is furnished*. To avoid this complexity, the clause is extraposed and is replaced by *it*, as in *It is a relief to learn that his new home is furnished*. The other factor is referential disambiguity, as reported by Mair [1990:33-40]. According to this factor, the avoidance of extraposition disambiguates a *for/to*-infinitive construction. In a sentence like *It is wicked for him to do so* there is hesitancy between interpreting *for him* as part of the main clause or part of the complement clause. To avoid this disambiguity, a non-extraposed variant with *for him* in clause initial position is used, as in *For him to do so is wicked*.

In Huddleston's [1988:452-3] viewpoint, the structural alternation is subject to some conditions. Extraposition is obligatory in two cases. The first case is with finite and *to*-infinitival complement constructions when the main clause has the operator (auxiliary)+subject order. This is instanced in *Is it necessary to tell her?* vs. **Is to tell her necessary?* Notice that *-ing* gerundial complement clauses can follow the operator, as in *Would recalling Smith serve any real purpose?* The construction may sound somewhat clumsy, but it is not ungrammatical. The second case is with verbs such as *appear*, *seem*, *chance*, *happen*, *remain*, and the passive of *hope*, *intend*, etc. This is instanced in *It appears*

⁹ In the transformational accounts of Rosenbaum [1967] and Edmonds [1976], the extraposed version is similarly assumed to be derived from the non-extraposed version.

that he left vs. **That he left appears*, and *It is hoped to follow this up in a later paper* vs. **To follow this up in a later paper is hoped*. Extraposition is rendered more difficult when the predicate is verbal. However, the present analysis sees nothing at all awkward about expressions such as *To teach young children requires great patience and vast experience* versus *It requires great patience and vast experience to teach young children*. As Kaltenböck [2004b] reports, verbal predicates are well attested with extraposed infinitives¹⁰.

4.1.3. Functional Distinction

As regards function, two factors determine the structural alternation. Non-extraposition is determined by a *given-before-new* factor, as suggested by Wasow and Arnold [2003:147]. According to this factor, the use of non-extraposition serves to link a subject clause which contains given information and has a strong anaphoric reference to the preceding context. Old information is more accessible at a number of levels, easier to produce early in the utterance, and needed to introduce the new information. In the light of this factor, the ordering *given-before-new* is posited as the neutral order of information in the clause and is meant to achieve coherence and facilitate comprehension. A sentence illustrating this pattern is *To win the cabinet's approval to his economic strategy is pivotal*. In this example, the speaker echoes what has been contextually debated, i.e., the topic of economic strategy.

By contrast, extraposition is determined by an *end-weight* factor, as proposed by Quirk et al. [1985:1355-1377]. According to this factor, the use of extraposition serves to place long and heavy constituents in the final position of a sentence so as to facilitate production. A concomitant factor is the *end-focus*, which places new information at the end of a sentence in order to give it prominence. An illustration of this pattern is *It is valuable to learn that brinkmanship reduces feelings of stress under pressure*. By using this pattern, the speaker achieves two purposes. First, s/he places the long and the complex constituent at the end. Second, s/he focuses on the new information concerning the reduction of stress. In doing so, the speaker is intent on facilitating the processes of utterance planning and production. The factors of short-old and long-new structures seem, as Arnold et al. [2000] write, to correlate. Short phrases with given referents tend to be easier to produce than longer phrases with new referents.

Let us summarise what has been said so far. When the information is given, it is more likely to be placed initially in the clause. Conversely, when the information is new, the more likely it is to be placed finally in the clause. Non-extraposition is used to achieve two purposes. First, it is used to achieve a balanced distribution of information within the construction. This happens when the complement clause is short and given in information, whereas the main clause is usually long and new in information, as in *To do nothing would lead either to getting the sack or to having a guilty conscience*. Second, it is used to create smooth transitions between constructions. This happens when a complement clause as in *To take his advice to heart is useful* refers anaphorically to a previous sentence like *He advises you to see a lawyer*. For more on constituent ordering in other areas of grammar, see Arnold et al. (2000) and the references cited therein¹¹.

¹⁰ For a detailed coverage of linear ordering in other areas of grammar, see Hawkins [1994].

¹¹ For more on the topic of extraposition from other perspectives, see Erdmann [1990], Collins [1994], Herriman [2000a/b], Kaltenböck [2004a/b, 2005], Miller [2001], Gómez-González [1997, 2001], among others.

4.2. Cognitive Account

The preceding discussions have furnished the factors affecting the use of either construction. According to the stylistic factor, non-extraposition is considered formal, whereas extraposition informal. In the light of the syntactic factor, extraposition should be used to avoid a heavy subject by moving it to the end of a sentence in accordance with the end-weight principle. In view of the functional factor, new information should be placed at the end of the sentence to receive focus. These factors seem to work for some cases in an account describing the problem under investigation. However, for an account to be comprehensive and adequate, these factors require the addition of the semantic factor. In CG, the syntactic structure of an expression directly reflects its semantic structure; thus they are indissociable. On this basis, the non-extraposed and extraposed instances are treated as distinct although they have the same conceptual content and their conceptualiser is generalised, defocused and implicit. Structural variants have different meanings resulting from different construals. In what follows, I will first introduce the basic notion offered by CG, and second show how the notion applies to the description of the pronoun *it*.

4.2.1. Scope

CG assumes a subjectivist account of linguistic semantics, which stipulates that the meaning of a linguistic expression includes both the knowledge system it evokes when the expression is activated as well as the particular construal the speaker imposes on its conceptual content. [Langacker 1997:4-5] *Construal* refers to the cognitive ability of the speaker to conceive a situation in alternate ways and to choose the appropriate structures in language to express them. Two expressions can have the same conceptual content, and only be different semantically by virtue of their choice of construal. Alternative expressions then represent different construals imposed on a conceptual content. The construals employed to structure situations amount to different mental experiences. Linguistically, these construals are mapped onto different linguistic realisations. Each linguistic realisation describes the same conceptual content, but does so in its own way. Therefore, the construal embodied by a linguistic expression constitutes a crucial facet of its meaning.

One relevant dimension of construal is *scope*. According to Langacker [1987:118-120], scope is the array of conceptual content that an expression evokes and relies upon for its characterisation. Scope contains the profile and represents the general focus of attention. It is vague and non-delimited in reference in that it comprises everything a conceptualiser is aware of at a given moment to assess the meaning of an expression. The conceptualiser's scope of awareness is what Langacker (to appear) refers to as *field*, i.e., everything evoked in describing a situation. An expressions's maximal scope is organised hierarchically with respect to prominence and relevance. The one with the highest degree of prominence and relevance is identified as *the immediate scope*, the general locus of viewing attention with respect to which an expression is interpreted. Considering Langacker's examples, the term *knuckle* evokes as its immediate scope the conception of *finger* for its characterisation. It is specifically the *finger* which is prominent and immediately relevant to the concept *knuckle*. The immediate scope is therefore describable as the context necessary for the characterisation of the profile.

The semantic distinction between extraposed and non-extraposed constructions is quite subtle but significant. The distinction is not based on the operation of generative rules; it is

exclusively a property of construal which gives the speaker the flexibility to construe his or her conceptualisation in alternate ways. Under this view, I argue that the choice as to which construction to use is motivated by the construal of *scope*, which is the array of conceptual content that an expression evokes and relies upon for its characterisation. One way in which the speaker exercises choice in construing a situation is by taking either a narrow or a *broad* view of it, which can change relative to the change of the aim he or she has in mind. In the narrow view, the speaker considers a minimal range of content in describing the situation. In the *broad* view, he considers a maximal range of content in describing the situation. The type of scope chosen is then deemed crucial for the characterisation of a given situation.

A non-extraposed complement construction takes a narrow view of a situation. The reason, I argue, is ascribed to the absence of a *field* represented by *it*. In this type of construal, the complement clause is considered the sole factor in inducing the experience in the speaker. That is, the reason for the experience expressed by the main predicate is unilateral, which is attributed solely to the complement content and does not involve anything else. By contrast, an extraposed complement construction takes a *broad* view of the situation. In this type of construal, the speaker considers all parts of a situation together in contributing to his or her experience, in which the complement content is the most important. It is the locus of factors inducing the experience in the speaker, and so the reason for the experience expressed by the main predicate is multilateral. The source of the speaker's experience in the extraposed construction is therefore somewhat larger in scope than in the non-extraposed one.

4.2.2. Application

To see the contrast, I will examine a range of constructions which are diverse enough to support the argument. In what follows, the constructions defocus the conceptualiser, and so tend to be construed in a generalised fashion. Given that the conceptualiser is implicit, and that English requires an overt subject, the constructions place other participants in such positions. In this respect, the language makes available two different construction types, each differing with respect to selection of grammatical subject. The predicates in the constructions can take as their subject either a complement clause or impersonal *it*. The contrast between the constructions is a matter of whether the trajector is identified as the complement clause or the experiential field represented by *it*. The constructions involve the same elements and describe the same situation; nevertheless they differ primarily in terms of which facets of the situation they highlight through the mental operation of *scope*. When the complement clause content is in focus, a non-extraposed construction is used. When the general circumstances are in focus, an extraposed construction is used¹².

Let us first consider the domain of evaluation, which I will exemplify by means of adjectival predicates expressing intellectuality, as seen in (4):

- (4) a. To argue about a trivial issue is unwise.
 b. It is unwise to argue about a trivial issue.

In the non-extraposed version in (4a), the complement clause is in profile and hence chosen as subject. The complement clause serves as the trajector of the adjective, and so is coded as subject. In this type of construction, the speaker takes a *narrow* view of the

¹² For a detailed discussion of the different domains evoked by the main complement-taking predicates used in *it*-construction, see Hamawand [2002].

complement event. Semantically, the content of the complement clause is considered the only stimulus that induces the evaluation. So, the reason for the evaluation is deemed unilateral, in the sense that the complement content is held solely responsible for the evaluation made by the speaker. The act of arguing about a trivial issue functions as a sole stimulus, and consequently induces a certain judgement by the speaker. A construction of this type simply highlights the role of the situation as target of evaluation. The reason is that in this type of construction the speaker's scope of awareness is limited.

In the extraposed version in (4b), the pronoun *it* is in profile and hence chosen as subject. The speaker's scope of awareness, i.e., *field*, profiled by *it* serves as trajector, and so is coded as subject. In this type of construction, the speaker takes a *broad* view of the complement event. Semantically, *it* represents a global stimulus subsuming the general circumstances which are responsible for the inducement of the evaluation.

The global stimulus embraces two components: the complement content which is central and the general circumstances surrounding its occurrence, including its consequences such as severing ties with people or distorting one's image in the eyes of people. So, the reason for the evaluation is deemed multilateral.

A construction of this type, which is introduced by *it*, subsumes the range of considerations that can be brought to bear for the evaluation. The reason is that in this type of construction the speaker's scope of awareness is non-delimited.

Adjectival predicates expressing intellectuality include *good/bad*, *(in)convenient*, *(un)fair*, *(il)legal*, *(il)legitimate*, *(il)logical*, *(in)sensible*, *(un)natural*, *(un)reasonable*, *(un)wise*, etc. This is shown in examples such as *To get more money for less work is unfair* vs. *It is unfair to get more money for less work* vs. *More money for less work is unfair (to get)*. The domain of evaluation involves other predicates expressing other meanings. Adjectival predicates expressing morality include *(in)appropriate*, *(in)correct*, *(in)decent*, *(un)ethical*, *(im)polite*, *(im)proper*, *(im)prudent*, *right*, *wrong*, etc. This is shown in *To wear a tie is appropriate* vs. *It is appropriate to wear a tie*.

Let us second consider the domain of modality, which I will exemplify by means of adjectival predicates expressing ease or difficulty, as seen in (5):

- (5) a. To make a momentous decision is tough.
- b. It is tough to make a momentous decision.

The difference in meaning between (5a) and (5b) rests on scope. In the non-extraposed option in (5a), the complement clause is chosen as subject. It represents a narrow view of the conceptualiser and functions as the sole stimulus in provoking the description. In the extraposed option in (5b), the global field or the immediate scope represented by *it* is chosen as subject. It represents a broad view of the conceptualiser and functions as a global stimulus subsuming all parts of the act in provoking the description. The parts include both the complement content which functions as a central component, and the general circumstances surrounding its occurrence. The source of the conceptualiser's description in (5b) is therefore somewhat larger in scope than in (5a). A list of adjectival predicates expressing difficulty or ease includes *difficult*, *easy*, *hard*, *plain*, *practicable*, *simple*, *tough*, etc.

The domain of modality involves other predicates expressing other meanings. Adjectival predicates expressing frequency include *common*, *customary*, *fashionable*, *habitual*, *rare*, *standard*, *traditional*, *usual*, etc. This is borne out by examples such as the following: *To*

see/Seeing tears at a farewell party is common vs. *It is common to see/seeing tears at a farewell party* vs. *Tears at a wedding are common to see*.

Let us third consider the domain of emotion, which I will exemplify by means of adjectival predicates expressing positive emotion, as seen in (6):

- (6) a. To remember old acquaintances is nice.
- b. It is nice to remember old acquaintances.

The non-extraposed variant in (6a) confers the focal status on the complement clause alone, and so assigns the entire complement clause the function of subject. In this construal, the complement clause is simply presented as a sole stimulus instigating the emotion in the conceptualiser. Merely the idea or the episode of remembering old acquaintances is sufficient to move the conceptualiser emotionally. The corresponding extraposed variant in (6b) confers the focal status on the global field, or the immediate scope, represented by *it*, and so assigns it the function of subject. In this construal, *it* represents the locus of the factors enticing the emotion in the conceptualiser. The factors include both the complement clause which serves as a central component, and the general considerations surrounding the act of remembering such as its effect on the viewer, his mind, his mood, etc. Such considerations are not directly available in the non-extraposed construction.

A collection of adjectival predicates expressing positive emotion includes *enjoyable*, *lovely*, *marvellous*, *nice*, *pleasant*, etc. Positive emotion can also be expressed by *-ing* participial predicates like *amusing*, *comforting*, *exciting*, *interesting*, *refreshing*, *satisfying*, *tempting*, *thrilling*, etc. This is manifested in terms of examples such as *To talk to people is interesting* vs. *It is interesting to talk to people* vs. *People are interesting to talk to*. A collection of adjectival predicates expressing negative emotion includes *awful*, *dreadful*, *horrible*, *ridiculous*, *terrible*, etc. This is illustrated by examples such as *To discuss sexual matters openly is horrible* vs. *It is horrible to discuss sexual matters openly* vs. *Sexual matters are horrible to discuss openly*. Negative emotion can also be expressed by *-ing* participial predicates like *alarming*, *disappointing*, *disconcerting*, *disturbing*, *embarrassing*, *irritating*, *shocking*, *terrifying*, etc. This is manifested in terms of examples such as *To see a rise in violent crime is alarming* vs. *It is alarming to see a rise in violent crime* vs. *A rise in violent crime is alarming (to see)*.

Let us fourth consider the domain of deontics, which I will exemplify by means of adjectival predicates expressing obligation, as seen in (7):

- (7) a. To follow the guidelines is mandatory.
- b. It is mandatory to follow the guidelines.

In the non-extraposed alternative in (7a), the whole complement clause is chosen as subject. The speaker takes a *narrow* view of the complement event, and considers its content the sole representative of the obligation. The guidelines, therefore, serve as the sole deontic force which renders the occurrence of the complement content necessary. In the extraposed alternative in (7b), the global field, or the immediate scope, represented by *it* is chosen as subject. *It* represents a global stimulus subsuming the general circumstances which surround the occurrence of the complement event. The speaker takes a *broad* view of the complement event, and considers all its parts together in representing the obligation. The parts include

both the complement content which functions as a central component, and the general circumstances surrounding its occurrence, its consequences whether direct or indirect, its effects whether immediate or distant, etc. The source of the speaker's evaluation in (7b) is therefore somewhat larger in scope than in (7a).

A handful of adjectival predicates expressing obligation includes *crucial*, *essential*, *imperative*, *incumbent*, *mandatory*, *necessary*, etc. The domain of deontics involves other predicates expressing other meanings. A handful of adjectival predicates expressing permission includes, *admissible*, *allowable*, *permissible*, etc. This is shown in examples such as *To make a certain level of error is allowable* vs. *It is allowable to make a certain level of error* vs. *A certain level of error is allowable*.

Let us finally consider the domain of epistemics, which I will exemplify by means of adjectival predicates expressing possibility, as seen in (8):

- (8) a. To win the game is possible.
- b. It is possible to win the game.

The non-extraposed instance in (8a) places the primary focus on the complement clause alone. The whole complement clause is made the primary figure in the profiled relationship, and so coded as the clausal subject. In this construal, the speaker often looks at the complement clause as being alone the subject of the possibility. The extraposed instance in (8b) shifts the primary focus away from the complement clause and places it on the global field expressed by *it*. *It* is made the primary figure in the profiled relationship, and so coded as clausal subject. *It* represents the immediate scope or the relevant scope of awareness, and therefore highlights the range of considerations that can be brought to bear for the possibility. In this construal, *it* brings into the picture clues of various kinds, which help the conceptualiser to expect that the complement event will happen. Such clues include, for example, the competitive spirit of the players, the strong support of the fans and the optimum atmosphere of the game.

Adjectival predicates expressing possibility include *possible*, *impossible*, etc. The domain of epistemics involves other predicates expressing other meanings. A constellation of adjectival predicates expressing certainty includes *clear*, *conceivable*, *evident*, *likely*, *obvious*, *probable*, *self-contradictory*, *true*, etc. This is shown in examples such as *That the project will succeed is likely* vs. *It is likely that the project will succeed*. Linguistically, the complement clause is rarely represented by the *to*-infinitive and often by the *that*-clause.

Certainty is also symbolised by predicates denoting impression such as *appear*, *seem*, etc. In atemporal complementation, the use of a non-extraposed construction is infelicitous as in **To be significant the difference appears*. Likewise, the use of an extraposed construction is infelicitous as in **It appears to be significant the difference*. This is so because predicates cannot exist on their own; there is a hole in their semantic structure which needs to be filled. With these predicates, the object noun phrase within the complement clause should always be placed in profile, and the complement clause should always come later, as in *The difference appears to be significant*. In processual complementation, these predicates do not occur in a non-extraposed construction as in **That the difference is significant appears*. The infelicity of the construction shows that the complement clause itself cannot per se constitute a stimulus to precipitate the judgement. Rather, they occur in an extraposed construction as in *It appears that the difference is significant*. The immediate scope profiled by *it* provides the

conceptualiser with a broader scope in precipitating the statement expressed in the complement clause.

In addition to adjectival predicates, nominal predicates also can take as their subject a complement clause or impersonal *it*. The predicates belong to one of the following domains.

- (i) Evaluation, difficulty as in *To complete work to standard and on time is a burden* vs. *It is a burden to complete work to standard and on time*; morality as in *To dodge a transport fare is an abuse* vs. *It is an abuse to dodge a transport fare*; intellectuality as in *To speak foreign languages is an advantage* vs. *It is an advantage to speak foreign languages*; and recurrence as in *To have a single child is a commonplace* vs. *It is a commonplace to have a single child*.
- (ii) Emotion, as in *To reach a compromise is a relief* vs. *It is a relief to reach a compromise*, and *To drive a car round a crowded city is hell* vs. *It is hell to drive a car round a crowded city*.
- (iii) Deontics, as in *To have a reasonable proficiency is a prerequisite* vs. *It is a prerequisite to have a reasonable proficiency*.
- (iv) Epistemics, as in *To travel round the world is a fancy* vs. *It is a fancy to travel round the world*. Besides, there are a few noun phrases which take as their subject either a complement clause or impersonal *it*. These include *a good idea, a good thing, an odd way, no use, no good, a bad taste, fair play, the fashion, a nasty surprise, a tragedy, a great disappointment, etc.* This is shown in *To try again is a good idea* vs. *It is a good idea to try again*.

Although they are rare, verbal predicates can also take as their subject a complement clause or impersonal *it*. The relative rarity of verbal predicates is the result of two factors. Syntactically, they are less likely to undergo extraposition because they are usually longer and contain more information than adjectival and nominal ones. Semantically, unlike adjectival and nominal predicates which are mostly stative, verbal predicates are dynamic. Verbal predicates belong to one of the following domains.

- (i) Evaluation, as in *To appear before a TV camera requires an effort* vs. *It requires an effort to appear before a TV camera*.
- (ii) Emotion, as in *To work abroad appeals to everyone* vs. *It appeals to everyone to work abroad*.
- (iii) Deontics, as in *To smoke in the building lies under the ban* vs. *It lies under the ban to smoke in the building*.
- (iv) Epistemics, as in *To get a job in a city stands a good chance* vs. *It stands a good chance to get a job in a city*.
- (v) Causation, as in *To see the scenery makes one happy* vs. *It makes one happy to see the scenery*.
- (vi) Quality, as in *To be a long-distance runner takes strength and stamina* vs. *It takes strength and stamina to be a long-distance runner*.
- (vii) Time, as in *To fix the washing machine takes three hours* vs. *It takes three hours to fix the washing machine*.
- (viii) Price, as in *To renovate a house costs a fortune* vs. *It costs a fortune to renovate a house*.

CONCLUSION

This paper has substantiated two fundamental tenets of CG. One tenet is that all elements posited in grammar are meaningful. The paper has shown that *it* is meaningful in all its uses, adding semantic import to the construction in which it appears. The meaning of *it* comprises a complex category with extended senses radiating from a prototype. Like any other lexical item or grammatical marker, *it* has both prototypical and peripheral senses. The prototypical sense relates to the physical domain, whereas the peripheral sense relates to abstract domain. Prototypically, it is used as a referring pronoun, referring back to something concrete like object, place, organisation, animal, etc. Extended from this is the sense when *it* refers back to something abstract like emotion, concept, state, situation, etc. Peripherally, *it* is used as a non-referring pronoun, profiling a setting, containing the content of a clause. Some settings are construed as profiling a physical area encompassing a particular event. Others are construed as profiling a mental space within which an event represented by a complement clause takes place.

The other tenet is that the form of a construction is characterised in terms of the construal imposed on its scene. *Construal*, is the ability to conceive and express a situation in different ways. Two types of construal apply to the analysis of *it*. One is *profile*, the conceptual unit within an expression which serves as a focal point. Linguistically, the profiled unit is represented by impersonal *it* and placed in subject position, designating a setting within which an event occurs. Another is *scope*, the range of conceptual content taken to describe a situation, which can be either *narrow* or *broad*. Linguistically, *narrow* scope is represented by a non-extraposed construction, where the speaker considers a minimal range of content in describing the situation. The small scope represented by the complement clause has been found to be solely responsible for the speaker’s evaluation. By contrast, *broad* scope is represented by an extraposed construction, where the speaker takes a maximal range of content in describing the situation. The large scope represented by both the complement clause and the general circumstances, profiled by *it*, have been found to be responsible for the speaker’s evaluation. The construal imposed on a scene is then the key element in explaining the specific form of a construction.

Table 1. Analyses of the impersonal pronoun it

Syntactic Analyses	Semantic Analyses	Cognitive Analyses
1. It is called a meaningless dummy pronoun. It is used to anticipate the subject. 2. It is called a meaningless expletive pronoun. It fills the gap left by the transformation of extraposition.	1. It is considered a meaningful morpheme. It has the property of ambience, i.e., it evokes the idea of generality. 2. It is as a cataphoric pronoun. It shows how important the referent in the upcoming discourse is going to be.	1. It is considered a presentational frame. It introduces a situation of some sort. 2. It profiles a field of awareness. It codes some kind of general circumstances surrounding an event.

Table 2. Functions of it in extraposed constructions

stylistic	<i>It</i> gives a construction the tinge of an informal style.
Syntactic	<i>It</i> allows moving heavy clauses to the end of a construction to facilitate production.
functional	<i>It</i> places new information at the end of a sentence to receive focus.
cognitive	<i>It</i> takes a broad view of a situation. It represents a global stimulus subsuming the general circumstances which are responsible for inducing the experience in the speaker.

The impersonal *it* has received different analyses. Each analysis is a reflection of the underlying assumptions of the theory it adopts. The table below summarises the analyses.

One construction in which the pronoun *it* occurs is referred to as extraposed. Its function in such a construction has also received different analyses. The table below summarises the analyses.

Chapter 75

**ICONICITY, SUBJECTIFICATION AND DOMINION
IN PORTUGUESE CONCESSIVE CLAUSES:
CONCEPTUAL DIFFERENCES
BETWEEN CONCESSIVE CLAUSES
INTRODUCED BY *APESAR DE* AND *EMBORA***

Rainer Vesterinen*

Stockholm University, Sweden

ABSTRACT

The present paper analyses Portuguese concessive constructions introduced by *apesar de* ('in weight of') and *embora* (from Old Portuguese *em boa hora*, 'in good time'). From the standpoint of Cognitive Grammar, it is argued that the constructions display a prime example of iconicity. Thus, it is shown that iconic principles such as linear ordering, formal complexity and formal distance explain the reason why the *apesar de* construction prototypically designates a more direct concessive relation, while the *embora* construction designates a more complex relation to the main clause. Further, it is claimed that the complex relation between the *embora* construction and the main clause represents a prime example of subjectification. Finally, the analysis shows that the subjunctive mood in the *embora* construction is related to the notion of dominion.

Keywords: cognitive grammar, concessive constructions, dominion, iconicity, subjectification

1. INTRODUCTION

The assumption that meaning is first and foremost related to lexicon, while syntax represents an autonomous component of language without meaning, is still dominant in much of current linguistic theorizing. During the last decades, however, functional and cognitive approaches to language and linguistic analysis have put focus on the relation between language structure and semantic meaning. For example, the model of Cognitive Grammar [Langacker 1987, 1991, 2008] puts forth that grammar (including syntax), lexicon and morphology represent a continuum of symbolic structures with inherent semantic meanings. Also, Haiman's [1980, 1985] studies on *iconicity* in language emphasize the relation between language structure and conceptual structure.

The perspective taken in the present paper is consistent with these latter approaches to linguistic analysis. Accordingly, the paper analyses finite and infinitive concessive clauses introduced by the prepositional expression *apesar de* ('in weight of') and by the conjunction *embora* (from Old Portuguese *em boa hora*, 'in good time') with the intention to ferret out the relation between the structural and semantic properties of these constructions. Throughout the paper, it will be shown that these structures reveal a noteworthy relation between language structure and semantic meaning.

It is a well-known fact that a fundamental property of concessive constructions is that they designate two events that in some way are incompatible with each other [cf. König 1986, 1988; Crevels 2000]. That is, one event is being brought about in spite of another event. This property has often led to the conception of a negated causal relation – the event expressed in the main clause is not accomplished *because* of the subordinate event, but *in spite* of it. The relation is frequently formalized as *although P, Q* [cf. Verhagen 2000; König and Siemund 2000]. The position taken in the present paper does not challenge this view. However, from a Cognitive Grammar perspective [Langacker 1987, 1991, 2008] of language, it will be shown that finite and infinitive Portuguese concessive constructions introduced by the prepositional expression *apesar de* and by the conjunction *embora* behave rather differently with respect to the canonical *although P, Q* formula.

The claim made is that the formal differences between these concessive clauses may find a conceptual explanation in notions like *iconicity*, *subjectification* and *dominion*. Thus, it will be shown that the formally weaker concessive clauses, introduced by the prepositional expression *apesar de*, prototypically designate a direct and observable concessive relation with the main clause event. On the other hand, the formally more complex concessive clauses, introduced by the conjunction *embora*, are more mental in character, frequently expressing the conceptualizer's reasoning and propositional attitude. In this sense, it will be shown that the clauses introduced by *embora* often deviate from the prototypical description of a concessive relation between two events.

The formal differences between Portuguese concessive clauses introduced by *apesar de* and *embora* are exemplified in examples (1-2) below:

- 1) ...Apesar de já passar da meia-noite, se
 ...PREP:CONC. already pass-INF. of midnight, CLITIC.PRON.
encontrava bastante gente.
 find-IMP: 3P.S quite people.

[Diário de Aveiro-N1483-1].¹

‘In spite of it being past midnight, there were quite a lot of people there.’

2) Este objectivo embora fosse meritório, revelava-

This objective CONJ:CONC. be-IMP.SUBJ: 3P.S praiseworthy, reveal-IMP: 3P.S.

se pouco interessante para a comunicação social.

CLITIC.PRON. little interesting to the mass-media.

[Diário de Aveiro-NO766-1].

‘This aim, although it was praiseworthy, proved to be of little interest to the mass media.’

One formal difference between (1) and (2) is related to the linguistic unit introducing the concessive clause – a prepositional expression in the first example and a conjunction in the second. Further, the prepositional expression in (1) is followed by an infinitive construction with the verb *passar* (‘to pass’). In Portuguese, this verb form does not express tense, but it may have personal inflection.² On the other hand, the conjunction *embora* is generally followed by a finite clause with the subjunctive mood of the verb (*fosse*), expressing both tense and person.

The hypothesis put forward in the present paper is that the formal differences attested above entail a difference in conceptual content. In accordance with Haiman [1980, 1985], I will show that the different structures with *apesar de* and *embora* are iconically motivated and that they, in fact, may be explained by the following iconic principles: (1) the principle of linear ordering, (2) the correlation between formal and conceptual complexity, and (3) the correlation between formal and conceptual distance. Hence, the formal difference between the two structures will reflect the conceptual differences.

Further, these conceptual differences will lead to a higher degree of subjectification in the finite structures than the infinitive structures. As will be shown throughout the analysis, the finite structures lend themselves to a more complex and elaborated communicative content than the infinitive structures. This conceptual content, often of a mental character, can be considered a prime example of subjectification. From Traugott’s perspective [1989, 1995, 1996] it subsumes internalization and propositional attitude; and from Langacker’s point of view [1990, 1999, 2003, 2006] it entails the mental scanning of a subjectively construed conceptualizer. This being so, it will be shown that concessive structures in Portuguese provide another noteworthy connection between linguistic iconicity and subjectification [cf. Vesterinen 2010a].

The analysis also aims at explaining the subjunctive mood in the finite concessive clauses. In doing so, special attention will be given to the notion of *dominion* [cf. Maldonado 1995; Vesterinen 2006, 2008]. The present paper will show that the subjunctive mood appears in grammatical contexts where the conceptual content of the subordinate clause is outside the conceptualizer’s (the main clause subject or the speaker) dominion. This may come about in two different ways: (1) the event does not belong to the conceptualizer’s *elaborated reality* [cf. Achard 1998], and (2) the conceptualizer has a restricted possibility to actively influence

¹ The examples in the present paper are from the Portuguese corpora Linguatca (Diaclav). The name of the journal from which the example is extracted is indicated between square brackets.

² The inflected infinitive is a typical feature of the Portuguese language. The verb form is formed by adding a suffixal subject morpheme on the plain infinitive in the following manner: 1p.s: -ø, 2p.s: -es, 3p.s: -ø, 1p.p: -mos, 2p.p: -des, 3p.p: -em.

and manipulate the described event [cf. Vesterinen 2010b]. This being so, I will argue that the semantics of the subjunctive is closely related to the notion of dominion.

Finally, the analysis of Portuguese concessive structures raises the question whether conceptual notions such as iconicity, subjectification and dominion may account for similar structures in other languages. An interesting case in point is the occurrence of different types of concessive clauses in English, i.e., concessive clauses introduced by *although*, *even if* and *even though*, on the one hand, and *in spite of* and *despite*, on the other. In fact, the difference between the former and the latter English concessive clauses bear some formal similarities with their Portuguese counterparts. This being so, it is very likely that the notions of iconicity, subjectification and dominion may shed some light over the conceptual meaning of English concessive clauses. A preliminary analysis will show that this may be a promising path for future investigation on English concessive structures.

The paper is organized in the following way: Section 2 discusses the notion of iconicity. Section 3 is dedicated to subjectification. Section 4 will furnish an explanation on the notion of dominion. The analysis of Portuguese concessive clauses with *apesar de* and *embora* is the topic of section 5. Section 6 provides a preliminary analysis of English concessive clauses. Finally, in section 7, some general conclusions will be offered.

2. ICONICITY

It is a common view that any given language consists of signs that do not necessarily resemble the referent that they designate. The relation between the sign and its referent is in most cases arbitrary. From a Cognitive Grammar perspective, the relation between a sign and the referent is understood as a symbolic relation between a semantic pole and a phonological pole, i.e., the linguistic expression [cf. Langacker 1987: 77]. In view of this fact, it may seem contradictory to claim that languages are iconic in character.

However, as Haiman [1980: 515] eloquently points out, this apparent contradiction may be explained by the notion of *diagrammatic iconicity*. To begin with, an iconic image displays a certain resemblance with its referent; prototypical cases would be a statue, a photograph or – in the case of human languages – onomatopoeic words. An iconic diagram, in contrast, is a systematic arrangement of signs that do not resemble their referent, but whose relationship with each other reflects the relationships of their referents. Put another way, a diagram does not resemble the concept that it represents, but it conveys a relation in which each symbol in the diagram represents a specific part of the concept. Correspondingly, linguistic symbols do not need to share any resemblance with the concept they represent. Nevertheless, the way we organize linguistic symbols (the grammar) is iconic: every symbol has a counterpart in the concept that it represents [cf. Haiman 1985].

Haiman [1985] presents two hypotheses related to the notion of diagrammatic iconicity. The first one, called *the isomorphism hypothesis*, states a *one-to-one correspondence* between a linguistic sign and its referent. The second one, known as *the motivation hypothesis*, states that the formal differences between two contrasting forms reflect their semantic differences:

The Isomorphism Hypothesis

Different forms will always entail a difference in communicative function. Conversely, recurrent identity of form between different grammatical categories will always reflect some perceived similarity in communicative function.

The Motivation Hypothesis

Given two minimally contrasting forms with closely related meaning, the difference in their meaning will correspond to the difference in their form [Haiman 1985: 19-20].

Obviously, the isomorphism hypothesis rejects the idea of full synonymy. Even though many linguistic signs share some semantic features, they will always entail some differences in communicative function. One example of this is found in the occurrence of different words designating a person with the feature [+MALE / +YOUNG] in English. Certainly, the words *boy*, *lad* and *guy* signal some communicative differences with respect to how we perceive the referent. It is also noteworthy that the second part of the isomorphism hypothesis may account for cases of polysemy – in cases where a form has more than one meaning, it is most likely that these meanings are related. In addition, the motivation hypothesis establishes a relation between linguistic forms and diagrams. If each part of a diagram represents a certain part of a concept, it is also very likely that each part of a linguistic form represents a certain part of a conceptualization. Thus, a difference in form between two minimally contrasting linguistic expressions will correspond to their different meanings.

The notion of diagrammatic iconicity is also present in Lakoff and Johnson [1980] and the metaphor [LINGUISTIC UNITS ARE CONTAINERS]. This metaphor precedes the expectations *more of form is more content* and *closeness is strength of effect*. The first expectation is an iconic relation in which the addition of linguistic units correlates with more content, while the second one is a relation between formal and conceptual distance. Let us consider some examples from Lakoff and Johnson [1980: 127-129]:

- 3) *He ran.*
- 4) *He ran and ran and ran and ran.*
- 5) *Mary doesn't think he will leave until tomorrow.*
- 6) *Mary thinks he won't leave until tomorrow.*

The semantic difference between (3) and (4) is rather obvious. The sentence *He ran* in (3) indicates that the subject was involved in the action of running, and would be considered as the “normal” way of indicating this kind of activity. The reduplication of the verb in (4), on the other hand, implies an extended activity, i.e., that the participant ran considerably more than in example (3). In the following example (5), the negative transportation places the negation further away from the predicate that it logically negates (*leave*) than in (6). This negative transportation is said to have the effect of creating a weaker kind of negation [Lakoff and Johnson, 1980: 129].

Another iconic relation, mentioned both in Lakoff and Johnson [1980] and Langacker [1987], is the way in which a successively greater formal distance between cause and effect correlates with a greater conceptual distance between cause and effect:

- 7) Sam killed Harry.
- 8) Sam made Harry die.
- 9) Sam caused Harry to die.
- 10) Sam brought it about that Harry died.

In these examples, a successively greater formal distance between the causal predicate and the one of effect tends to signal a more indirect (or diffuse) causation. In (7), for instance, the juxtaposition SN + V + SN signals a prototypically direct causal relation, while, in (10), the greater distance between these linguistic units implies an indirect one. Langacker [1987] comments on this phenomenon with the following words: “Such paradigms indicate that greater phonological distance between a predication of cause and one of effect correlates with greater conceptual distance in the domains of cause-effect linkages” [Langacker 1987: 181].

To summarize, the notion of iconicity rests on the assumption that linguistic forms and structures can be understood as diagrams. Thus, the isomorphism hypothesis posits a one-to-one correspondence between form and meaning, and the motivation hypothesis defends the idea that formal differences reflect conceptual ones. If we relate these hypotheses to infinitive and finite concessive clauses with *apesar de* and *embora*, the result is that these clauses cannot be regarded as synonymous. First, one form corresponds to one meaning. Secondly, the formal differences will reflect some conceptual differences.

3. SUBJECTIFICATION

Subjectification as a linguistic phenomenon has primarily been analysed from two different – and in some cases competing – perspectives in cognitive and functional approaches to linguistic analysis [cf. Traugott 1989, 1995, 1996; Langacker 1990, 1999, 2003, 2006]. Traugott focuses mainly on the diachronic aspect of subjectification and defines it as “the historical pragmatic-semantic process whereby meanings become increasingly based in the speaker’s subjective belief state or attitude towards what is said...” [Traugott 1996: 185]. In other words, the notion of subjectification is very much equated with the speaker’s subjective judgement and propositional attitude towards the proposition. In Traugott’s framework, the path towards subjectification involves three tendencies:

Tendency 1: Meanings based in the external described situation > meanings based in the internal (evaluative, perceptual, cognitive) described situation.

Tendency 2: Meanings based in the external or internal described situation > meanings based in the textual and metalinguistic situation.

Tendency 3: Meanings tend to become increasingly based in the speaker’s subjective belief/state toward the proposition [cf. Traugott 1989: 34-35].

An example of Tendency 1 is the shift in meaning of *boor* (farmer > crude person). Another is the Old English *felan* that initially only had the meaning “touch” and did not acquire a perceptual meaning until late Old English. Both cases imply a shift from a concrete domain to an abstract domain. Tendency 2 includes the development of morphological and lexical forms into connectives coding the textual situation and the shift from mental-state to

speech-act verb meaning, i.e., *observe* (perceive > state that). Finally, Tendency 3 is exemplified by the shift of the temporal adverb *while* into a concessive, and the development of the action verb *go* to have a temporal meaning of immediate planned future [cf. Traugott 1989: 34-35].

Langacker [1990], analysing the notion of subjectification mainly from a synchronic point of view, defines it as “the realignment of some relationship from the objective axis to the subjective axis” [Langacker 1990:13]. This definition relates to the asymmetry between *the ground* (in the subjective axis) and the object of conception (in the objective axis) as a matter of *construal* and *perspective*, dimensions that include notions like *vantage point* and *viewing arrangement*. The term *ground* is used for the speech event, i.e., the speaker, the hearer and the time and place of speaking. The speaker is the primary subject of the conceptualization (the conceptualizer). The ground is said to be subjectively construed when left “offstage” as an unprofiled facet of the speaker’s conceptualization. The object of conception is objectively construed if it is well delimited from the ground. A finite clause has the effect of maximizing the asymmetry between the subject and the object of conception [cf. Langacker 1990: 14-15].

In more recent works, Langacker [1999, 2003, 2006] has redefined subjectification as semantic *bleaching* or *fading away*. The mental scanning of a subjectively construed entity is there all along and emerges – or becomes more evident – when the object of conception “is no longer there to mask it” [Langacker 2006: 21]. Put another way, the mental scanning of the ground is constantly present, but becomes more obvious when the described situation lacks objective movement. This situation is exemplified in (11-12) with the different senses of the preposition *across*:

- 11) A giant chicken marched angrily across the street.
- 12) There’s a KFC outlet right across the street.

The first example (11) describes a situation where the subject successively occupies all the positions indicated by the prepositional phrase *across the street*. Evidentially, the ground is also scanning this situation as it occurs as an offstage participant of the objective scene. In (12), however, there is no longer any objectively construed movement. The subject (*a KFC outlet*) is occupying a single location, i.e., the end of the path described by *across the street*. The only thing moving is the ground, which is scanning mentally along the path in order to localize the KFC outlet. The difference between (11) and (12) is illustrated in Figure 1.

In the moving sense of *across*, illustrated in (A), the ground (G) scans the objective scene, i.e., the movement of the subject that is crossing the street. The movement of the subject is illustrated by the connected circles that traverse the landmark (the street). In contrast, there is no physical movement to be scanned in the static sense of *across*. The objective scene lacks motion. That is, the objective movement in (A) has been replaced by subjective movement in (B). It is the conceptualizer, as subject of conception (the ground), that mentally scans along the path with the intention of locating the subject (*a KFC outlet*). As Athanasiadou *et al.* (2006: 3) point out, this shift constitutes a change in the locus of activity. It is now the conceptualizer, and not the subject, who is the active participant. This phenomenon, also termed *attenuation* in Langacker’s framework, is a fundamental trait of subjectification, and involves a loss of subject control and a shift in domain from an active subject to the conceptualizer [cf. Langacker 1999].

Figure 1. Subjectification of across [cf. Langacker 2006: 23].

Despite the differences, both Traugott's and Langacker's approaches to subjectification will be considered in the present study. In the first place, it is very likely that Tendency 1 and Tendency 3 in Traugott's approach to subjectification are relevant features in the variation between infinitive and finite concessive clauses with *apesar de* and *embora*. This will be confirmed in a higher degree of internalization and personal beliefs in the finite clauses than in the infinitive ones. In the second place, the claim made in this paper is that the finite concessive clauses often display inferential features. That is to say, the conceptualizer shows evidence of personal inferences about how the world is shaped. This subsumes that a subjectively construed conceptualizer is mentally scanning between two events that do not need to have any visible relation in the outside world. This is understood to be Langacker's view of subjectification.

4. DOMINION

The term *dominion* refers to the relation between a conceptualizer, on the one hand, and an event or a proposition, on the other. The notion was primarily established in order to account for possessive relations as a component of the *reference-point model* [cf. Langacker 1991: 169-172]. Analysing the complexity of possessive constructions, Langacker [1991] states that the schematic meaning of possessive constructions is related to the existence of two entities in the same cognitive domain. Thus, abstract possessive relations like: *We have a lot of animals in this region* may be explained in the same manner as more prototypical possessive relations, e.g., *My car*. The common denominator is the existence of two entities in the same cognitive domain.

Maldonado [1995] builds on the reference-point model and on the notion of abstract possession, proposing that not only things but also propositions and events are candidates for entering into the conceptualizer's dominion as "possessed" entities. The author connects this feature to the notion of *elaborated reality* [Achard 1998]. If an event or a proposition is a part of the conceptualizer's conception of reality, the event (or the proposition) is located in the dominion of this participant. The conception of reality as evolving through time, rather than as a stable component, subsumes that not only the history of events is considered in relation to reality but also not yet realized events. That is, our knowledge of how the world has

evolved until now gives us the confidence to predict future events as more or less integrated in our conception of reality.

This tendency is reflected in expressions like *I know that Mary will come*, *We will go to Spain this summer* and *I will go to work tomorrow*. The history of events provides us with the conviction that the future event will happen. For example, I may have had an earlier conversation with Mary in which she promised to come, or I may have made plans to go to Spain with my family this summer. Finally, the habit of going to work five days a week makes it rather easy to predict that I will go there tomorrow as well, provided some unplanned event does not alter the course of events. In sum, our experience as human subjects living in the world makes it possible to integrate future events into our conception of reality and, thus, into our dominion.

Obviously, some events are excluded from the conceptualizer's conception of reality. If the evolution of the past (until now) has not favoured the occurrence of these events, it is not very likely that the conceptualizer will regard them as a part of his conception of reality. In these cases, when the conceptualizer is not committed to the event as a "real" entity, the event is located outside the dominion of the conceptualizer. Figure 2 illustrates the difference between events located inside or outside the conceptualizer's dominion:

a)

Inside.

b)

Outside.

Figure 2. Events located inside and outside the conceptualizer's dominion.

The circle with the letter (C) indicates the conceptualizer. In a multi-clausal expression, this participant is normally equated with the main clause subject. That is, an expression like *Peter thinks it will rain*, expresses the conceptualization of the main clause subject. Thus, the event is in the dominion of this participant. This situation is illustrated in (A). On the other hand, the expression: *Peter does not think it will rain* designates that the event is located outside the dominion of the main clause subject (Figure 2B). Obviously, the speaker is the conceptualizer of the linguistic expression, but the main clause subject is the

conceptualizer of the subordinate event [cf. Langacker 2004]. As for concessive constructions, the analysis in the present paper will show that the concessive relation is primarily considered from the vantage point of the speaker. Hence, the speaker is the conceptualizer of the concessive relation.

Another facet of events located inside or outside the conceptualizer's dominion refers to his/her capacity to actively manipulate and influence the described event. Langacker [2004] uses the term *control cycle* in order to describe this experience and points out that: "being alive is to function as actor in control cycles, interacting with the environment to gain control over certain facets of it" [Langacker 2004: 537]. That is, events that we are able to control are located inside our dominion. Evidently, there are a lot of events in our daily life that we can actually influence and manipulate. If I am hungry, I can easily choose to do something about it, if I am tired, I can take a nap etc. Socially, we establish stable relations with certain rules and expectations that increase the notion of control. In the same way that the history of events makes it possible to predict or exclude future events, the social organization of human life entails that we have the possibility to exert control over some events and have a lesser degree of control over others.

At this point, two interrelated questions need to be clearly spelled out. First, the notion of dominion does not refer to an objective world "out there" that is independent of human conceptualization. Rather, it is the relation between the conceptualizer and the described event that is in focus. Put in other words, the notion of dominion highlights the relation between the conceptualizer and the conceptualized event. This relation is further expressed by linguistic means. Thus, the way in which the conceptualizer describes the event also shows how he/she conceptualizes it in relation to the notion of dominion. In this sense, the conceptual content of the main clause directs focus to the relevant dominion. The following examples may illustrate the question:

- 13) It is raining.
- 14) I do not believe that it is raining.
- 15) I know that it is raining.
- 16) It is a pity that it is raining.

At a first glance, the first example (13) seems to be neutral regarding the notion of dominion. However, the conceptualizer integrates the event into his/her conception of reality. The main clause of example (14), on the other hand, explicitly expresses that the subordinate event is located outside the epistemic dominion of the conceptualizer. This is indicated by the negation of the main clause verb ('*believe*'). The reverse situation is at hand in (15). The main clause expression *I know* also directs focus to the epistemic dominion, but the expression designates an event that is located inside the conceptualizer's epistemic dominion. Finally, example (16) designates an event that is inside the epistemic dominion of the conceptualizer. However, the main clause *It is a pity* designates the conceptualizer's attitude towards the complement event. Consequently, the conceptual content of the main clause directs focus on the conceptualizer's *dominion of active control* – and the fact that the conceptualizer has a restricted capacity to influence and manipulate the event.

It is noteworthy that examples like (13-16) are related to mood choice in Portuguese. If the main clause designates that the complement event is inside the conceptualizer's epistemic dominion, the complement event is described with the indicative mood. Thus, expression like

I know, I believe, I think etc. take an indicative complement. If the conceptualizer, on the other hand, does not incorporate the main clause event in his/her epistemic dominion, the subjunctive mood is chosen. Therefore, the negative counterparts of *I know, I believe* and *I think* take a complement in the subjunctive mood. Furthermore, the subjunctive mood appears in factive contexts. Expressions like *it is a pity, I regret* and *it is a shame* take a subjunctive complement. The common denominator for these expressions seems to be that they designate that the complement event is outside the conceptualizer's dominion of active control [cf. Vesterinen 2010b].

In sum, the notion of dominion is not related to an objective reality, but to the relation between the conceptualizer and the outside world. Further, the way in which the notion of dominion is evoked depends on the linguistic context. If the linguistic context refers to the conceptualizer's epistemic position towards the event, the epistemic dominion is evoked. If it refers to the conceptualizer's personal attitude towards the event, the dominion of active control is evoked. Therefore, there is no request for both facets of dominion to be equally considered. Rather, the linguistic context evokes different dominions.

5. APESAR DE AND EMBORA: ICONICITY, SUBJECTIFICATION AND DOMINION

The linguistic material consists of 300 cases that have been extracted randomly from the Portuguese corpus *Linguatca*. Each construction is represented with 150 examples. It should be made clear that there is no clear-cut division between the analysed concessive clauses in this section. The APESAR DE CONSTRUCTION may occasionally designate conceptual meanings that are prototypical for the EMBORA CONSTRUCTION. Likewise, the EMBORA CONSTRUCTION may be used in contexts that are typical of the APESAR DE CONSTRUCTION. However, the analysis will show that there is a strong tendency for the two constructions to display totally different conceptual meanings.

5.1. Iconic Motivation

The sequential relation between the two events in a concessive relation is reflected by the formula *although P, Q*. That is, the event described in the concessive clause is sequentially prior to the event described in the main clause. This is not surprising, bearing in mind that the concessive clause expresses an obstacle that precedes the event in the main clause temporally. This being so, the formula *although P, Q* captures the iconic principle of linear ordering – the linear order of the formula parallels the sequential order of the events [cf. Haiman 1980]. Relating this phenomenon to Portuguese concessive constructions introduced by *apesar de* and *embora*, it is noteworthy that the constructions differ substantially regarding their position in relation to the main clause.

In fact, there is a strong tendency for *apesar de* to precede the main clause. The initial position exhibits 111 occurrences, while the final position only presents 39 occurrences. In contrast, the construction with *embora* shows the opposite pattern: only 40 examples precede the main clause, while the final position is at hand in 110 cases. A Chi-square test shows that

the association between the type of concessive construction and its position is considered to be extremely statistically significant, $X^2 = 65.336$, $df = 1$, $p < .0001$ (two-tailed). The results are shown in Table 1.

Table 1. The position of the concessive clause

	Initial position	Final position	Totals
Apesar de	111	39	150
Embora	40	110	150
Totals	151	149	300

Thus, the concessive construction with *apesar de* reflects the prototypical temporal order of events in a concessive relation. On the other hand, the construction with *embora* is totally opposed to this tendency, being preceded sequentially by the event that it is obstructing. In other words, if the construction with *embora* designates a concessive relation, this relation is not considered in relation to the ordering of events in the outside world. The analysis that follows will show that this is actually the case. Rather than expressing a concessive relation in the outside world, the construction introduced by *embora* gives evidence of the speaker's (conceptualizer's) attitude towards the main clause event. Even though this relation may have concessive features, it is more mental in character.

The formal position of the concessive construction has other iconic effects. In fact, the initial position of the construction with *apesar de* creates a formal closeness between the events described in the main and concessive clauses. On the other hand, the conjunction *embora* creates a formal distance between the events. The difference is exemplified below:

- 17) *Apesar de*: Prepositional expression + infinitive clause + main clause.
- 18) *Embora*: Main clause + conjunction + finite clause (subjunctive).

Thus, if formal structure reflects conceptual structure, which is a fundamental claim within the cognitive linguistic framework, the iconic principles of linear ordering, formal complexity and formal distance would entail that the formal differences between the constructions with *apesar de* and *embora* reflect their communicative differences. The formal closeness between the events described by the APESAR DE CONSTRUCTION and the main clause verb would reflect conceptual closeness. The linear order would reflect the canonical succession of events in a concessive relation. Finally, the formal complexity of the finite concessive construction would mirror conceptual complexity.

Table 2, below, corroborates this claim. In most cases, the clause introduced by *apesar de* designates a prototypical concessive relation with the main clause event. That is, the main clause event is brought about in spite of the concessive event. This relation is verified in 114 examples. The EMBORA CONSTRUCTION, on the other hand, only exhibits 54 occurrences with this feature. Instead, the latter frequently designates the speaker's reasoning and propositional attitude towards the main clause event, thus creating a mental concessive relation between the conceptualizer and the main clause event. Further, it often designates a circumstance that is related to the main clause event, not in a purely concessive relation, but a hypothetical one. The association between the type of concessive construction and its relation to the main

clause is considered to be extremely statistically significant, $X^2 = 47.091$, $df = 1$, $p < .0001$ (two-tailed). The results are shown in Table 2.

Table 2. The concessive relation

	(+) concessive	(-) concessive	Totals
Apesar de	114	36	150
Embora	54	96	150
Totals	168	132	300

The following examples with the APESAR DE CONSTRUCTION illustrate the tendency for the construction to designate direct concessive relations that are observable in the outside world:

19) Apesar de não conseguir eleger um deputado, a CDU
 PREP:CONC. not succeed-INF. elect-INF. a deputy the CDU
subiu de 2,74 por cento, em 1995, para 3,54 por cento.
 rise-PRET: 3P.S of 2,74 percent, in 1995, to 3,54 percent.
 [Diário de Aveiro-N1046-1].

‘In spite of not being able to elect a deputy, CDU rose from 2.74 percent in 1995 to 3.54 percent.’

20) e apesar de se estar perante uma actividade ilegal,
 and PREP:CONC. CLITIC.PRON be-INF. before an activity illegal
os empresários arriscam e, em muitos casos, preferem
 the businessmen risk-PRES: 3P.P and, in many cases, prefer-PRES: 3P.P.
pagar as coimas que lhes são aplicadas.
 pay-INF. the fine that them be-PRES: 3P.P enforce-PART.
 [Diário de Aveiro-N1433-1].

‘And in spite of knowing that it is an illegal activity, the businessmen take the risk and, in many cases, they prefer to pay the fine that they are given.’

21) Apesar da empreitada já ter sido concluída, a
 PREP:CONC. contract already have-INF. be-SUP. completed, the
artéria ainda não foi pavimentada.
 artery yet not be-PRET: 3P.S pave-PART.
 [Diário de Aveiro-N1058-1].

‘Although the contract had been signed, the arterial road has not yet been paved.’

The common denominator for the examples above (19-21) is that they display concessive relations that are related to events, states or affairs in the outside world. In (19), the relation is of the type: not succeed in electing a deputy > rise in popularity. In the following example (20), the concessive relation is between the events of knowing that an activity is illegal, on the one hand, and choosing to perform that activity, on the other. Finally, example (21) displays a relation between a business deal that is completed and the lack of fulfilling the terms of the business deal.

Another striking feature of the construction with *apesar de* is the great quantity of cases containing the perfect construction. The quantitative analysis reveals that 51 (34%) of the 150 cases with *apesar de* contain the perfect construction, while the EMBORA CONSTRUCTION only exhibit 16 cases with this feature. Moreover, the semantics of the perfect construction is frequently considered in terms of *current relevance* [cf. Carey 1996; Dahl and Hedin 2000; Langacker 1991]. It is used in contexts in which the described event has some immediate consequences at the time of speaking.³ This being so, it is expected that the use of the perfect construction in concessive clauses tightens the concessive relation between the events, designating a more direct relation. The following examples may illustrate this direct relation:

22) Apesar de nos últimos anos não se terem verificado
 PREP:CONC. in the last years not CLIT.PRON. have-INF: 3P.P verify-SUP.
acidentes de monta, mandam as regras da segurança e
 accidents of mayor, order-PRES: 3P.P the rules of security and
da modernidade avançar-se.
 of the modernity advance-INF. CLITIC.PRON.
 [Diário de Aveiro-N0995-1].

‘Although there have only been a few accidents verified during the last years, they have decided to develop the security rules in the name of modernity.’

23) Apesar de ter efectuado uma segunda parte bem melhor,
 PREP:CONC. have-INF. make-SUP. a second part good better,
continuou a perder muitos ressaltos para o adversário.
 continue-PRET: 3P.S to lose-INF. many rebounds to the rival.
 [Diário de Aveiro-N1146-1].

‘In spite of having had a much better second half, the team still lost many rebounds to the other team.’

In fact, the use of the perfect construction in the examples above (22-23) seems to create a strong concessive relation between the two events. In (22), for example, the construction is used in an iterative context that conveys the idea of repeated events (or non events) that are opposed to the main clause event. That is, a reduced number of accidents have been witnessed during a period of time, including the time of speaking. In spite of this fact, the main clause subject decides to increase the security. Example (23) expresses a similar aspectual meaning. In this case, however, the temporal proximity between the concessive event and the main clause event is even stronger. That is, in spite of the improvement in the second half of the game, the team loses many rebounds to the other team. In sum, examples (22) and (23) convey the idea of concessive events that are utterly relevant for the main clause event – and for the concessive relation between the two events. Prototypically, the relation refers to events that are observable in the outside world.

³ See Paiva Boléo [1936], Costa Campos [1997] and Ilari [1997] for detailed studies on the Portuguese perfect construction and its relation to the moment of the uttering. Of special interest is the notion that the effect of the event described by the perfect construction persists in the reference time of the uttering, and that the perfect construction expresses repeated occurrences of an event.

The following cases show that the concessive construction with *embora* deviates rather substantially from the prototypical concessive relation. Rather, it designates events and circumstances pertaining to reasoning and propositional attitudes:

24) Recorde-se que este cargo de arcebispo

Remember-PRES.SUBJ: 3P.S CLITIC.PRON that this post of archpriest

só pode ser desempenhado por presbíteros embora

only can-PRES: 3P.S be-INF perform-PART. by priests CONJ:CONC.

os diáconos também participem na votação.

the deacons also participate-PRES.SUBJ: 3P.P in the voting.

[Diário de Aveiro-N0793-1].

'Remember that the post as archpriest is reserved for priests, even though deacons may participate in the voting.'

25) A vitória do Valonguense não sofre qualquer.

The victory of the Valonguense not suffer-PRES: 3P.S any

contestação, embora o Pinheirense...merecesse pelo

contestation, CONJ:CONC. the Pinheirense...deserve-IMP.SUBJ: 3P.S for the

menos o chamado golo de honra.

less the called goal of honour.[Diário de Aveiro-N1887-1].

'The victory of Valonguense is undeniable, even though Pinheirense deserved a consolation goal.'

26) Desta feita, um empate pode selar o compromisso

Of this made, a draw can-PRES: 3P.S seal-INF. the commitment

inicial, embora não seja de desprezar a possibilidade

initial, CONJ:CONC. not be-PRES.SUBJ: 3P.S. of despise the possibility

de um triunfo dos locais.

of a victory of the locals.

[Diário de Aveiro-N0689-1].

'Thus, a draw will mean that they have lived up to their initial expectations, even though one cannot exclude the possibility of a victory for the locals.'

27) Manuel Farias, presidente da junta de Ágeda não têm

Manuel Farias, Chairman of the committee of Ágeda not have-PRES: 3P.S

dúvidas em afirmar que o impacto positivo é maior,

doubts in declare-INF. that the impact positive be-PRES: 3P.S bigger,

embora reconheça que traga alguns

CONJ:CONC. admit-PRES.SUBJ: 3P.S that bring-PRES.SUBJ: 3P.S some

inconvenientes.

inconveniences.

[Diário de Aveiro-N0630-1].

'Manuel Farias, Chairman of the committee of Ágeda does not hesitate to point out that the positive impact is greater, even though he admits that it will lead to some inconvenience.'

Interestingly, examples (24-27) exhibit a more diffuse relation between the main clause and the concessive clause. In fact, the concessive clause introduced by *embora* does not designate a prototypical concessive relation between events. In (24), the relation is: the post is reserved for priests > deacons may vote. In (25), the concessive clause is related to the conceptualizer's personal opinion about *the consolation goal* and not to the fact that the victory was beyond doubt. Further, example (26) does not designate an observable concessive relation, but the conceptualizer's calculation about future events. Finally, the performative *reconhecer* ('admit') in (27) designates the conceptualizer's personal attitude towards the main clause event, and not a concessive relation in the world. This being so, it is the conceptualizer's reasoning and personal attitude towards the main clause event that is in focus, not the concessive relation between two events. This feature certainly entails a higher degree of subjectification in the EMBORA CONSTRUCTION than in the one introduced by *apesar de*. This feature will be the topic of the subsequent section.

5.2. Subjectification

The previous section focused on iconic principles such as linear order, formal complexity and formal distance. Thus, it was shown that these principles, in fact, may explain the conceptual differences between the APESAR DE and the EMBORA CONSTRUCTION. The present section will go one step further, proposing a relation between iconic principles and subjectification. That is, a higher degree of formal complexity – and formal distance to the main clause – in the EMBORA CONSTRUCTION will entail a higher degree of subjectification. Examples (24-27) in the previous section illustrated this tendency. The following examples may also serve as an illustration:

28) Mas é importante realçar que o mérito é

But be-PRES: 3P.S important highlight-INF. that the merit be-PRES: 3P.S

dos árbitros, embora seja verdade que os dirigentes

da subida.

of the rise.

[Diário de Aveiro-N0185-1].

‘Even though he did not reveal exact figures from the budget, he did not hesitate to point out that it is in line with the demands of inflation.’

It is interesting to note that the relation between the concessive clause and the main clause is more related to the conceptualizer’s personal judgements than to concessive relations in the world. In example (28), the concessive clause designates how the conceptualizer evaluates the main clause event. In order to do so, the conceptualizer creates a situation that he/she considers to be opposed to the main clause event. Thus, the concessive relation is more related to the conceptualizer’s propositional attitude than to observable events in the world. This also holds for the subsequent example (29). The conceptualizer contrasts a main clause event that occurs in the outside world with his own reflection about the main clause event. That is to say, the conceptualizer creates a concessive relation between an event and his/her personal opinion regarding this event.

This tendency may be more emphasized. In many cases, the EMBORA CONSTRUCTION occurs in hypothetical contexts with a future projection. This feature was prominent in example (26). The following examples share this feature:

30) ...Ao Beira Mar apenas interessa a conquista de três pontos,
 ...To the Beira Mar only interest-PRES: 3P.S the conquest of three points,
que não garantem permanência porque os aveirenses
 that not guarantee-PRES: 3P.P the permanency because the Aveiro team
embora ultrapassem os adversários de hoje,

 in the table league, stay-PRES: 3P.P with the same number of
 (31) *de pontos.*

(31) of points.

[Diário de Aveiro-N0110-7].

‘The main aim for Beira Mar is to win three points, which however does not guarantee that they will escape relegation: even if the teams from Aveiro win against their opponents today, they will stay at the same position in the league table (31).’

31) Vamos aguardar pelo desenrolar da prova,
 Go-PRES: 1P.P look forward-INF. for the unwind-INF. of the test,
embora todos os indicadores apontem para que
 CONJ:CONC. all the indicators point-PRES.SUBJ: 3P.P to that
estejamos na presença de uma competição de
 be-PRES.SUBJ: 1P.P in the presence of a competition of
grande nível.
 big level.

[Diário de Aveiro-N0766-1].

‘We are looking forward to the development of the test, even though everything indicates that we will confront a high level of competition.’

This being so, a fundamental difference between the APESAR DE CONSTRUCTION and the EMBORA CONSTRUCTION relates to the character of the concessive relation. Prototypically, the former designates concessive relations between two observable events. The latter, on the other hand, tends to designate a relation between an event and the conceptualizer's propositional attitude regarding the event. This situation is indeed compatible with the notion of subjectification. From Traugott's perspective, the EMBORA CONSTRUCTION does not describe external properties of the described event, but internal (mental) ones. Further, the internalization equates with the conceptualizer's subjective belief state towards the proposition. Langacker's perspective of subjectification subsumes a loss of subject control and the mental scanning of a subjectively construed conceptualizer. This situation emerges in cases where the concessive clause does not designate an observable event, but the conceptualizer's propositional attitude towards the event. That is, in accordance with Figure 1, movement in the outside world is replaced by the conceptualizer's mental scanning.

A remaining question is why the EMBORA CONSTRUCTION and not the construction with *apesar de* displays subjectification. The most plausible answer to this question is that the tense feature of the finite verb has a grounding effect, i.e., that it locates the described event in relation to the ground (the speaker, the hearer and the circumstances of the speech event). As Langacker [1991] points out, one fundamental difference between grounded and ungrounded events is that the former create a relation to the conceptualizer's conception of reality and, thus, to his/her propositional attitude. The fact that verbs of propositional attitude like *know*, *think*, *believe* and *realize* take *that*-clauses is a direct consequence of this phenomenon. The complement event is grounded in relation to the speaker's conception of reality. On the other hand, verbs that designate perception (*see*, *hear*, *feel*) take infinitival complements. This is not surprising, given the fact that the event is observable in the outside world. Thus, the event does not need to be grounded.⁴

Relating the concessive clauses with *apesar de* and *embora* to the effect of grounding, it is interesting to verify a correlation. A concessive relation between events that are observable in the world does not need to be grounded. Thus, the prototypical conceptualization of these events is expressed by the use of the APESAR DE CONSTRUCTION. In contrast, propositional attitudes and mental experiences cannot be seen in the outside world. Hence, they need to be grounded. So, the EMBORA CONSTRUCTION creates this relation to the ground – and to the conceptualizer's mental world. In the subsequent section, it will be shown that the effect of grounding is highly relevant to the notion of dominion.

5.3. Dominion

The examples offered in previous sections revealed that the EMBORA CONSTRUCTION frequently occurs in hypothetical contexts in which the conceptualizer makes a prediction about future events. This feature was salient in examples (26), (30) and (31). For convenience, the English translation of these examples is given below:

⁴ However, it is interesting to note that these verbs take a *that*-clause when they designate the conceptualizer's mental experiences and inferential structures [cf. Vesterinen 2007].

- 32) ...Even though one cannot exclude the possibility of a victory for the locals.
 33) Even if Aveiro win against their opponents today...
 34) ...Even though everything indicates that we will confront a high level of competition.

The examples displayed above (32-34) share an interesting connection with other grammatical contexts in which the subjunctive mood occurs in Portuguese. The subjunctive mood appears in contexts where the conceptualizer is not committed to the truth of the proposition. For example, expressions like *não creio* ('I do not think/believe'), *duvido que* ('I doubt'), *é possível* ('it is possible that') and *é provável* ('It is probable') take a that-clause in the subjunctive mood. The subjunctive mood is, thus, connected to grammatical contexts in which the described event is located outside the conceptualizer's epistemic dominion. Consequently, it is not difficult to understand the reason why it appears in hypothetical contexts with the EMBORA CONSTRUCTION – it signals that the event is outside the conceptualizer's epistemic dominion. The following example may illustrate this tendency:

- 35) Mário Saldanha espera ter os pavilhões cheios,
 Mário Saldanha hope-PRES: 3P.S have-INF. the sports halls full,
embora em Faro o horário possa condicionar
 CONJ:CONC. in Faro the schedule can-PRES.CONJ: 3P.S condition-INF.
esse aspecto.
 this aspect.
 [Diário de Aveiro-N0333-1].
 'Mário Saldanha wishes to have full sport halls, even though the schedule in Faro may have an effect on this.'

In example (35), the EMBORA CONSTRUCTION designates the conceptualizer's personal beliefs regarding the possibility of having full sport halls. Even though this participant demonstrates an inclination towards rejecting the proposition, given the schedule of the event in Faro, he/she does not fully embrace the conceptual content of the EMBORA CONSTRUCTION. This being so, the EMBORA CONSTRUCTION frequently seems to designate events that are located outside the epistemic dominion of the conceptualizer [cf. also examples 26, 30, 31].

This automatically leads to occurrences presenting a direct concessive relation between two events. The character of these occurrences may at first sight create difficulties. Actually, the concessive clauses tend to describe an event that is outside the conceptualizer's dominion of active control – not only in the EMBORA CONSTRUCTION, but also in the APESAR DE CONSTRUCTION. The subsequent examples illustrate the problem:

- 36) *Apesar de discordar da estratégia, nunca deixou de*
 ...PREP:CONC. disagree-INF. of the strategy, never leave-PRET: 3P.S of
ter uma colaboração leal com o partido.
 have-INF. a cooperation loyal with the party.
 [Diário de Aveiro-N0622-1].
 'Although he disagreed about the strategy, he was always loyal to the party.'

37)...*O nosso concelho, embora ainda tenha carências,*
 ...The our county, CONJ:CONC. still have-PRES.SUBJ: 3P.S deficiencies,
já possui condições para se poder dar
 already own-PRES: 3P.S conditions to CLITIC.PRON. can-INF. give-INF.
este luxo.
 this luxury.
 [Diário de Aveiro-N1074-1].

‘Although our county still has its deficiencies, it has already shown such good potential that we can allow ourselves this luxury.’

Both (36) and (37) describe concessive events that are located outside the conceptualizer’s dominion of active control. In the first example (36), the fact that the subject in the concessive clause disagreed with the party about the strategy implies passionate discussions on the topic. It also implies that the speaker did not succeed in changing the ideas of the subject in the concessive clause. In (37), the concessive clause highlights the deficiencies of the region. This situation is opposed to the conceptualizer’s desire, but his/her force to actively change the situation is restricted. This being so, both the APESAR DE CONSTRUCTION and the EMBORA CONSTRUCTION designate events located outside the conceptualizer’s dominion.

However, it is pertinent to consider and contrast the semantic meaning of the infinitive and the subjunctive. By describing an event taking place in the world, the conceptualizer may choose to either describe the occurrence of the event or add his/her personal perspective on the event. Once again, this distinction relates to the effect of grounding. Given that events are visible in the outside world, they do not need to be grounded by a finite clause. On the other hand, thoughts and propositions about events are not observable in the outside world. For that reason, they need to be grounded. Therefore, the APESAR DE CONSTRUCTION describes an event, while the EMBORA CONSTRUCTION goes one step further. It not only describes an event, but it also describes the conceptualizer’s perspective on the event.

Furthermore, the subjunctive mood is closely related to grammatical contexts where the described event is located outside the conceptualizer’s dominion of influence and active control (cf. section 4). This being so, it is not difficult to understand the reason why it appears in certain concessive clauses. In contrast, the infinitive does not focus on this feature, but designates the mere occurrence of an observable event in the outside world. Therefore, the APESAR DE CONSTRUCTION and the EMBORA CONSTRUCTION highlight the iconic relation between grammatical structure and conceptual structure. Further, the EMBORA CONSTRUCTION provides evidence for the claim that the meaning of the subjunctive mood is closely related to the notion of dominion.

6. THE RELATION TO ENGLISH CONCESSIVE CLAUSES

The analysis offered so far confirms an iconic relation between infinitive and finite concessive clauses in Portuguese. Formally more complex concessive clauses correlate with conceptually more complex concessive relations, including the conceptualizer’s reasoning and propositional attitude towards the concessive relation. This being so, the finite clauses

also display a higher degree of subjectification than the infinitive clauses. Moreover, the analysis confirms that the subjunctive mood is consistent with the fact that concessive clauses prototypically are located outside the conceptualizer's dominion. On the other hand, infinitive concessive clauses tend to designate observable events in the outside world. In this section, a preliminary analysis of English concessive clauses will show that the notions of iconicity, subjectification and dominion may prove to be relevant in order to understand the conceptual content of English concessive structures.

It is a well-known fact that English concessive clauses are introduced by a conjunction taking a finite clause or by a prepositional expression taking a noun phrase or the progressive form of the verb. Common examples of the concessive conjunctions are *although*, *even if* and *even though*, while the prepositional expressions *despite* and *in spite of* are representative examples of the latter. A plausible hypothesis is that the occurrence of different structures is motivated by the conceptual content that they may evoke. The following examples are cases in point:

- 38) This is why she felt compelled to go behind his back and do the things that she did, although I do not excuse her actions. [www.enotes.com].
- 39) We'll enjoy church festival even if it rains. [www.worcesternews.co.uk].
- 40) My tax dollars also go to keep prisoners on death row even though I think the death penalty is morally wrong. [globalcomment.com].
- 41) In spite of the bad weather, we are going to have a picnic. [mtamrinh.blogspot.com].
- 42) Taiwan Democrats lose despite winning most votes.[www.fnfasia.org/index.].

Thus, the common denominator for the finite concessive constructions (38-40) is that they designate the conceptualizer's reasoning and propositional attitude towards the main clause event. That is, even though the relation may have concessive features, these are related to the conceptualizer's mental world and not to concrete manifestations in the outside world. In (38) and (40), the conceptualizer's involvement is particularly salient, expressing his/her opinion regarding the event described in the main clause. Furthermore, it is interesting to compare example (39) with (41). In fact, the finite expression *even if it rains*, in example (39) does not designate that it actually is raining, but is a hypothetical statement about a future event. In contrast, the prepositional concessive clause *in spite of the bad weather* designates a concrete situation. This feature is also at hand in example (42). The two clauses designate a concessive relation in the outside world: win most votes > lose elections.

The conceptual differences attested above reflect the iconic nature of language. The finite constructions are able to express thoughts and propositions about events taking place in the outside world, given their grounding effect, while non-finite constructions tend to describe concrete manifestations in the outside world. Consequently, this entails a higher degree of subjectification in the finite clauses. Instead of describing a concessive relation with real-world features, the concession is related to the conceptualizer's reasoning and propositional attitude towards the main clause event, which includes the mental scanning of a subjectively construed conceptualizer. Also, the difference between examples (39) and (41) highlights the

notion of epistemic control. That is, the finite concessive clause frequently refers to events that do not belong to the conceptualizer's conception of reality.⁵

This latter feature is also related to the possibility of inserting modals in the concessive clause. It is perfectly natural to use modals in concessive structures introduced by *although*, *even if* and *even though*. On the other hand, the use of modals in concessive structures that are introduced by prepositional expressions like *in spite of* or *despite* is more problematic. And as Langacker [2008] points out: "the absence of a modal indicates that the profiled process is accepted by the speaker as real (the result phase), and the presence of a modal, that it is not" [Langacker 2008: 162]. This being so, the finite concessive structures – and not the non-finite ones – are related to the notion of dominion, more exactly to the notion of epistemic control.

CONCLUSION

The present paper has shown that iconic principles such as linear ordering, formal complexity and formal distance may explain the conceptual differences between Portuguese concessive clauses introduced by *apesar de* and *embora*. The linear ordering of the APESAR DE CONSTRUCTION and the main clause correlates with that of a direct concessive relation. Moreover, the formal complexity and the greater distance to the main clause in the EMBORA CONSTRUCTION reflect conceptual complexity and distance. That is, the latter construction does not merely describe a concessive relation, but a more elaborated one that includes the conceptualizer's propositional attitude. Consequently, the APESAR DE CONSTRUCTION and the EMBORA CONSTRUCTION also display a relation between iconicity and subjectification. A higher degree of formal complexity and distance in the latter prototypically matches a higher degree of subjectification. Finally, the mood choice has been explained by the notion of dominion. The infinitive construction describes a direct concessive relation without focusing on this aspect. The subjunctive mood, on the other hand, signals that the concessive event is located outside the conceptualizer's dominion.

As a final point, the analysis offered in the present paper may not be exclusively related to the difference between finite and infinitive concessive structures in Portuguese. In fact, it is very likely that future investigations of concessive relations and different concessive structures in English may confirm the same conceptual patterns. That is, the concessive conjunctions followed by a finite clause are conceptually more elaborated than their infinitive counterpart. Although the preliminary analysis offered in the present paper needs to be further elaborated, it indicates that this may be the case.

Chapter 76

SEEM*: EVIDENTIAL, EPISTEMIC, OR WHAT ELSE? A STUDY IN COGNITIVE SEMANTICS

Günther Lampert

Johannes Gutenberg-University Mainz (JGU), Germany

ABSTRACT

This paper, firmly anchored in the framework of Leonard Talmy's cognitive semantics, reconstructs a core semantics of the English verb *seem*, which is considered a central instantiation of the schematic system of cognitive state. This 'new' semantics is meant to overcome the indecisiveness of recent accounts how to categorize *seem* (and its equivalents in other European languages): either as evidential or as epistemic or as both, and concomitantly identifying the meaning of *seem* with the meaning of the various constructions of which it is a constituent. To this end, the semantics of *seem* is here associated with Talmy's concept of the comparison frame, which places alternative conceptualizations of a situation within a single frame. In the case of *seem*, these alternatives are either 'fictive' or 'factive', juxtaposed in an ambiguous figure-ground configuration, which may be disambiguated by what in Talmy's ongoing research on the attention system in language is called non-dedicated lexical triggers (like *really*, *just*, *merely*, *only*). Conceived of as an incentive for further investigations of how schematic systems are 'recruited' to integrate, the paper at the same time testifies to the explanatory power of Talmy's Overlapping Systems Model of Cognitive Organization.

Keywords: cognitive semantics, *seem*, evidentiality, epistemic modality, overlapping systems model of cognitive organization

* This article is an expanded version of a lecture given at the 9th China International Forum on Cognitive Linguistics (CIFCL 9), Beijing, on July 6, 2011, <http://cifcl.buaa.edu.cn/>. Many thanks for inviting me to the Forum go again to its organizer, Thomas Fuyin Li.

1. INTRODUCTION

At the beginning of this study on the semantics of *seem* I will refer to Shakespeare: The first occurrence of *seem* in Shakespeare's *Hamlet* has in fact become quite famous; critics argue that it addresses one of the main topics of that play, or even of Shakespearean drama in general—the opposition of appearance and reality. The passage in question relates to Hamlet's actual first entry—when the new king of Denmark, Claudius, asks Hamlet (after he has returned from Wittenberg to mourn the sudden death of his father): “How is it that the clouds still hang on you?”¹, and Hamlet replies: “Not so, my lord, I am too much in the sun.” Then, Queen Gertrude, Hamlet's mother, intervenes:

(1) *Queen*: Good Hamlet, cast thy nighted colour off And let thine eye look like a friend on Denmark. Do not for ever with thy vailed lids Seek for thy noble father in the dust. Thou knowst 'tis common all that live must die, Passing through nature to eternity.
Hamlet: Ay, madam, it is common. *Queen*: If it be Why seems it so particular with thee?
Hamlet: ‘Seems’, madam—nay it is, I know not ‘seems’.
 ‘Tis not alone my inky cloak, cold [good] mother, Nor customary suits of solemn black, Nor windy suspiration of forced breath, No, nor the fruitful river in the eye, Nor the dejected haviour of the visage, Together with all forms, moods, shapes of grief, That can denote me truly. These indeed ‘seem’, For they are actions that a man might play, But I have that within which passes show, These but the trappings and the suits of woe. (I.ii: 66-86)

This is, as the renowned critic Terry Eagleton has argued, above all a metalinguistic speech, where Hamlet “riddles and bamboozles his way out of being definitely known” (1986: 71). The evidence of outward ‘show’, the ‘as if’ of the action being played out, will mislead people's judgments on Hamlet's ‘true’ personality. Using a term that Leonard Talmy has introduced into cognitive linguistics, I will refer to how Hamlet *seems* to others as “fictive”, and how he really *is* as “factive” (Talmy 2000.1: 100). This tension between fictivity and factivity constitutes, I will suggest in this paper, the core semantics of *seem* in all its uses. This will no doubt be a controversial view because it contrasts with all current accounts of *seem* (and its equivalents in other European languages) in that it focuses on the lexical semantics of *seem*, rather than on the semantics of *seem*-constructions, and it rejects the proliferation of senses that comes as a corollary to the constructional approach.² Most of these studies also assume that *seem* is a, or rather the prototypical marker of (inferential) evidentiality, and that it is, at the same time, an instantiation of epistemic modality, expressing a less than definite commitment of the speaker/writer toward the factuality of a proposition. As in my preferred framework, Leonard Talmy's cognitive semantics, evidentiality and epistemic modality are conceived of as subcategories of a schematic system called cognitive state³, *seem* would thus be a marker of cognitive state. In this vein, the article is meant as a contribution to what can be known about the system of cognitive state. At the

¹ All quotes from *Hamlet* follow the Third Arden Edition [2006], which is based on the Second Quarto of the play.

² Cf. Aijmer (2009); Cornillie (2007a, b); De Haan (2007); Gisborne and Holmes (2007); Diewald and Smirnova (2010a, b).

³ Cf. Talmy (1988b: 200).

same time, however, it tries to unhinge its semantics from the categories of evidentiality and epistemic modality.

To this end, I have structured my paper in the following way: In strong support of George Lakoff's (1990: 146) dictum that there can be no arguments about conclusions if there is no agreement on premises, I will, in a first section, detail the concepts of cognitive semantics I need for my investigation. In siding with Talmy's conceptual semantics and his emphasis on the attentional primacy of the simplex morpheme over the construction⁴, my paper is also meant to be read as a contribution toward reinstating *conceptual* semantics as a major concern of cognitive semantics, perhaps as a partial antidote to the presently mushrooming usage-based cognitive linguistics accounts that yield tables, numbers, and more and more sophisticated statistics⁵. Since my study on the core semantics of *seem* is committed to cognitive semantics, my method is, in line with Talmy (2007c), primarily that of analytical thought, but not exclusively so: as my account will have a special focus on co-occurrence patterns, the data I adduce in my argumentation are all corpus-based; they are taken from Mark Davies' *Corpus of Contemporary English*⁶ and the *World Wide Web*.

In section two, I will direct my attention to the two categories of evidentiality and epistemics, setting them conceptually apart, as has become common practice in the expert literature, but likewise exploring the various ways they may become related. In that section I will also briefly delineate how evidentiality and epistemics have come (or not come) to be conceptualized in cognitive linguistics.

The central section three will present a case study of what I consider the core semantics of *seem*. In doing so, I will take account of the (alleged) semantic syncretism that is supposed to be a major characteristic of "epistentials" like *seem* and *appear* (see Faller 2002: 87). Scrutinizing typical co-occurrence patterns of *seem* with evidential and epistemic adverbs and modal verbs will cast some doubt not only on the assumption that *seem* is either epistemic or evidential, but also on the 'both-and' view. Instead, the paper will suggest a semantics for *seem* and *appear* that has recourse to such cognitive semantics notions as fictivity/factivity, figure/ground, and, in particular, the construct of the comparison frame⁷. Finally, in applying fragments from Talmy's ongoing research on attention, a selected class of adverbs will be re-analyzed as so-called (non-dedicated) triggers that make one of the alternative conceptualizations juxtaposed in a comparison frame more salient.

A concluding section will sum up my line of reasoning—a cognitive semantics approach that basically tries to implement Talmy's idea that different cognitive systems may be recruited⁸ to interact in constituting a cognitively motivated semantics of *seem* in *all* its constructional variants.

⁴ Cf. Talmy, forthcoming: "That is, the simplex morpheme, whether or not a construction grammar might hold it to exist in theory as a unit, may nevertheless have cognitive status as the prototype of a linguistic symbol and to be generally more salient than a construction [...]." I sincerely thank Len Talmy for giving me access to a substantial portion of his yet unpublished research on attention in language.

⁷ The concept of the comparison frame has first been introduced in Talmy's (1996a) article on the windowing of attention (cf. Talmy 2000.1: 291).

⁸ Cf. Talmy (2011) for some ideas about schematic systems' potential interactions.

2. THE FRAMEWORK: COGNITIVE SEMANTICS

As stated before, my paper explicitly subscribes to Leonard Talmy's cognitive semantics, especially to his concept of the Overlapping Systems Model of Cognitive Organization, which is meant to describe how the mind works "at what is now often called higher levels of cognition" (Talmy 2006: 253). This model of cognition includes

- substantive systems, such as perception, motor organization, culture, and language,
- operational systems applying to the substantive systems—attention, memory, perspective.

These systems then function with respect to organized domains, like the spatial, the temporal, and the causal domains, which in turn may be conceived of as cognitive systems themselves. The result of this specific cognitive architecture is the Overlapping Systems Model of Cognitive Organization, which presumes that there may be differences or identities or degrees of overlap between these systems. Importantly, this specific architecture is a defining characteristic of Talmy's concept of cognitive linguistics, setting it apart from competing views within cognitive linguistics that summarily associate language with general cognition⁹.

Turning now to one of the major cognitive systems, language, it has been Talmy's long-standing research agenda to give a precise description of the concept structuring system of language as it is first and foremost expressed in the system of a language's closed class forms. This concept structuring system of language has a hierarchical structure—starting out from basic concepts via conceptual categories to the large-scale schematic systems that Talmy has so far reconstructed¹⁰. Such schematic systems consist of a selection of basic concepts in a particular arrangement of categories. To this date Talmy has recovered the following schematic systems in language:

- three so-called architectonic systems: configurational structure, perspective, and attention;
- the system of force dynamics, which addresses the forces exerted by and the causal interactions among entities marked out by the first three systems. Force dynamics is relevant for the present paper because it is the semantic category that "most uniquely characterizes the grammatical category of modals as a whole, both in their basic and in their epistemic usages" (Talmy 2000.1: 409);
- and, finally, Talmy has repeatedly mentioned that there is a large-scale fifth system, which he names the system of cognitive state. This system will occupy center stage in this paper;

Though it has not been scrutinized in such detail as the other four systems, Talmy has given us a sketch of what the conceptual substance of this system might be. Definitely it will have to comprise several subsystems. One of them is the epistemic system, "which covers characterizations of a sentient entity's states of knowledge" (Talmy 2006: 259-260); the

⁹ See, for instance, Langacker (2008: 8).

¹⁰ A spelled-out account of this hierarchical organization can be gained from Talmy (2005).

epistemic system is gradient in nature, and its values range from certainty to uncertainty. Other subsystems of the cognitive state system that Talmy refers to are the agency system (covering volition and intention), expectation, and the affect system in language.

While Talmy's focus has so far been mainly on the first four systems' structure and their patterns of operating, research might now proceed to investigate into these systems' interaction and integration.

3. EPISTEMICS: EVIDENTIALITY AND EPISTEMIC MODALITY

3.1. Evidentiality in Talmy's System of Cognitive State

If the epistemic system (as part of the system of cognitive state) has been analyzed at all in cognitive linguistics, it has been done so almost exclusively with regard to describing the epistemic senses of the modal verbs (mostly of English but also of other languages); here the hegemonic view has been to view these senses either as a mapping of force constellations (cf. Talmy 1988a) from the socio-physical domain into the epistemic domain (cf. Sweetser 1990), or in terms of the so-called evolutionary momentum of reality, which itself links up with the corresponding notion of subjectification (cf. Langacker 1991, 2008).¹¹ None of these—not necessarily mutually compatible—accounts provides any thorough treatment of evidentiality, though. Apart from Floyd (1999), a typologically motivated account of evidentiality which selectively applies notions from Langacker's cognitive grammar but is otherwise based on the then current typological studies¹², evidentiality has only been touched upon in an interview with Leonard Talmy published in the *Annual Review of Cognitive Linguistics* (cf. Talmy 2006). In that interview, Talmy (2006: 260) explicitly conceives of evidentiality as a subsystem of epistemics—along with “indicative-subjunctive type distinctions, factivity, forms of probability and possibility, and the like”. For Talmy, epistemics itself is, as I stated earlier, a major division within the system of cognitive state, covering sentient entities' states of knowledge. The evidential markers found in many languages of the world are, according to Talmy, to be located either at the certainty end of the gradient of epistemic certainty or, minimally, at the ‘considered probable’ end; certainty is thus correlated with ‘knowing’, and factuality and ‘considered probable’ with ‘inferring’ and likelihood of the stated proposition. In general, then, all evidential systems are, in Talmy's (2006) view, positively skewed toward the occurrence of the event or, in slightly different terms, toward the veridicality of the stated proposition. It is worth mentioning that Talmy uses the term proposition here—a by no means uncontested concept in cognitive linguistics (presumably because of its association to truth-conditional theories of meaning). Following Johnson (1987: 3), proposition might be considered a “pattern of experience or understanding, with sufficient internal structure to permit inferences.” Thus conceived, the term may find a legitimate place in cognitive semantics as well.

¹¹ All of this is meanwhile well known, and the details need therefore not be spelled out again; summary accounts may be found in Radden (1999); Günther Lampert and Martina Lampert (2000); De Mulder (2007); Mortelmans (2007).

¹² Cf. Bybee (1985); Chafe (1986); Anderson (1986); Willett (1988).

Note also that, in Talmy's conception, factivity (or veridicality) is *not* identical with factuality: while the term factuality displays connotations of truth, factivity is a genuinely cognitive concept (cf. Talmy 2000.1: 100). As to the difference between 'knowing' and 'inferring', they can be kept apart if one assumes that there are divergent 'bases' for concluding either the proposition's factuality or its likelihood (cf. Talmy 2006: 261). Thus, the speaker, in using some evidential strategy, has three bases for concluding the factuality of the proposition (which, recall, is correlated with 'knowing that'): she can witness the reported event, as in *John was out chopping wood—I saw him*. The speaker can perform the action in question herself, as when she herself states *The beads are now on the string*, knowing that she herself has been responsible for the stated result; or the factuality of the proposition derives from what is considered common knowledge, as in Talmy's example *Horses eat grass*. The 'considered-probable' value in the gradient of epistemic certainty is, by contrast, based on inference. Here, Talmy distinguishes several subtypes:

- The speaker has non-visually perceived the event; the standard example is *John must have been out chopping wood—I heard the whacks coming from the forest*. Worth mentioning is that Talmy in his 2006 interview considers epistemic *must* to be an evidential marker¹³.
- The speaker observes some piece of evidence, as in *John must be out chopping wood—the ax is missing from the house*. We note that the respective 'reading' of *must* as a special subtype of inferential evidentiality is here 'triggered' by elements of the context (the missing ax), serving as some kind of backward pointing attentional 'cue' that guides the hearer to 'select' the intended reading from potentially available competing ones. Alternatively, however, one might perceive this contextual cue to provide the necessary evidentiary 'strength' for the selection of *must* (as against, say, *may*).
- the speaker observes periodicity (a subtype which is only found in Talmy's sketch of evidentiality, not in the special literature on evidential subtypes): *John must be out chopping wood—it's 3 PM and he usually chops wood now*.¹⁴

These first three subtypes show that in such evidentially marked situations the evidence itself is not expressed in the marker but only in the context. Experts may recall Chafe (1986: 266) claiming that in cases of inferential evidentiality the evidence need not be specified. Such observations have prompted Günther and Martina Lampert (2010: 318) to submit the term contextual evidentiality to account for such evidential strategies as have been instantiated in Talmy's first three subtypes.

In the fourth type, where the evidence is based on hearsay, it is specified in the marker itself. Talmy's example *John is said to be chopping out wood* makes this sufficiently transparent. In this first subtype of hearsay, the mode of evidence is clear from *is said to* alone—the hearer or reader does not need any further contextual cues. And in a second hearsay subtype it is, as a complement, not the mode of evidence but the source that gets specified: in English, there is *according to*, as in, to modify Talmy's standard example a bit,

¹³ This view is likewise found in De Haan's recent re-readings of epistemic *must*—see De Haan (2009), and, earlier, Mortelmans (2000) on German *müssen* and *sollen*.

¹⁴ Surveys of the pertinent typologies are found in Squartini (2001) and Wiemer (2008).

*According to Fred, John is out chopping wood.*¹⁵ If it is supposed to be criterial for an evidential marker that the specific type of evidence be part of the core semantics of the marker, then these two reportative subtypes would be more prototypical evidentials than the markers of inferential evidentiality¹⁶.

While Talmy's remarks are, even in the sketchy form they are presented in the 2006 interview, among the most detailed statements about evidentiality in the cognitive linguistics literature, this is, of course, not the whole story about evidentiality¹⁷. What these notes have clearly revealed, though, is that the question 'where does evidentiality reside?' becomes indeed crucial for a description of the semantics of evidential markers.

That cognitive linguists have been relatively silent about the category of evidentiality may find its explanation in the fact that in English, their preferred object language, evidentiality is a lexical, not a grammatical category—which in a very influential strand of research has been deemed sufficient enough for not considering English a language in which evidentiality is a relevant category in the first place¹⁸. Research not only on grammaticalized but also on lexicalized evidentiality has indeed become vital in the last few years—mainly from a functionalist point of view¹⁹. Before I turn to my case study, it therefore appears necessary to briefly present what may be called the consensus view on evidentiality.

3.2. What the Experts Say: Notes on Evidentiality

Evidentiality is considered a conceptual category that has come to be described in wider and narrower senses²⁰. Most specialists would probably subscribe to Aikhenvald's (2003: 1) working definition: "Evidentiality proper is understood as stating the existence of a source of evidence for some information; that includes stating that there is some evidence, and also specifying what type of evidence there is." One may further distinguish between the source or the type of evidence and the mode how this information is obtained²¹. The source of information refers to the knowledge system by which the information is acquired; it can be external or internal to the speaker²². By contrast, the mode of information names the type of process leading to the acquisition of the information: it can be directly visual (or any other sensory mode like seeing, hearing, touching)²³, indirectly through inference, or it can be reports of various kinds (instances of mediated evidentiality²⁴). Moreover, we need to distinguish between a conception of evidentiality where it is just relevant that (or whether) the

¹⁵ On hearsay markers in European languages cf. now Wiemer (2010).

¹⁶ See Günther Lampert and Martina Lampert (2010) for details.

¹⁷ Cf. e.g., Cornillie (2007), which is, to date, the most detailed account of evidential verbs in a cognitive grammar framework—though it also has a strong grounding in functional grammar.

¹⁸ The most prominent advocate is Alexandra Aikhenvald; cf. Aikhenvald (2003, 2004, 2007). It must be added that her radical view on the grammar-lexicon divide is by no means shared by everybody in the community of evidentiality experts; see, e.g., Wiemer (2008, 2010a).

¹⁹ Cf., however, von Stechow and Gillies (2010) from the perspective of formal semantics.

²⁰ For a critical view on parameters used in definitions of evidentiality see Günther Lampert and Martina Lampert (2010).

²¹ The differentiation of source and mode derives from Squartini (2001), (2008).

²² This difference is now recast in terms of the notion of (inter-)subjectivity; cf. Cornillie (2007a, b) and, especially, Nuyts (2001).

²³ Cf. Günther Lampert, forthcoming.

²⁴ For the term see Plungian (2001).

stated proposition can be related to some piece of evidence, and a more specific one where the type or mode of evidence is supposed to be specified²⁵.

This difference may be re-conceptualized in terms of a distinction between ‘knowing that’ and ‘knowing how’. English examples of the which-type would be *this is visibly/tangibly/palpably/audibly false*, where the (sensory) mode of evidence is clearly specified in the adverbs. Other examples of the which-type instantiate mediated evidentiality, such as *it is said, s/he is said to*. For an expression to be considered an evidential marker of English, the that-type, however, seems to be sufficient. All the core stance adverbs mentioned in the literature to mark out evidentiality belong in this subcategory: *obviously, allegedly, apparently, evidently*. But, as Simon-Vandenberg and Aijmer (2007) reveal, none of these adverbs appears to have a clear preference for a specific type of evidence, and some of them are probably not evidential markers at all²⁶.

Yet, the conceptualization of evidentiality solely in terms of the that-type yields some problems. If this type should be sufficient for membership in the category, how would we have to interpret assertions like *He is tired*? They are, *qua* assertions, based on some evidence, or relate to some information source, even if it might be the (subjective) feelings or beliefs of the speaker: for any state of knowledge must come from somewhere. So, if categorical assertions are to be included as members of the category of evidentiality, it will ultimately become a gratuitous category. This need not ensue, however, because there is a difference between categorical assertions and their associated propositions and evidentially marked propositions. Distinguishing between these two types would, for the first time in my survey, invoke the attention system of language. While it may indeed be so that in our world all categorical assertions need some evidence as their knowledge base, this is, at least in English, not made linguistically overt; or, to phrase it in Talmy’s terms: in categorical assertions evidentiality is not attentionally windowed but remains in the background of attention. In Talmy’s new factor model of attention²⁷, the notion of windows of attention will be recast in more general terms as one basic principle of attention: it is the attentional principle of presence that makes the difference here.

Also, it could be argued that any evidentially marked proposition invariably expresses only a weakened commitment to the veridicality of the stated proposition; in other words, the marked proposition would always have to be ‘less’ committed to the factuality of the stated proposition than an unmarked categorical assertion. If this were a valid assumption, it would follow that when you say *she is obviously tired* it may in fact not be so obvious; or, there may be no or at least no sufficient or shared evidence available to communicate the information in the form of a categorical assertion. Reformulated in terms of epistemic certainty, one might argue that you only say you are certain when you are not—in the same vein as you only give reasons when an alternative is deemed necessary.²⁸

²⁵ Compare Aikhenvald’s (2003) definition cited above.

²⁶ *Clearly*, for instance; see Wiemer and Stathi (2010: 279).

²⁷ See Talmy (2007a).

²⁸ See Talmy (2000.1: 291-292).

3.3. Epistemic Modality

If it may still be premature to present a consensus definition of evidentiality, specialists more readily seem to agree on what epistemic modality is supposed to be about: it is instantiated by expressions whose semantics refers to such notions as ‘degree of certainty’ or ‘speaker’s commitment to the truth of the proposition’²⁹. Of course, the notions employed in the definitions reveal (as has already been shown in Lampert and Lampert 2000) that the research tradition in the area of epistemic modality has always been strongly rooted in modal logic. This becomes apparent even in the following quote from Nuyts (2001: 21), perhaps the most detailed functional-cognitive account of epistemic modality:

“Epistemic modality is defined [...] as (the linguistic expression of) an evaluation of the chances that a certain hypothetical state of affairs under consideration (or some aspect of it) will occur, is occurring, or has occurred in a possible world which serves as the universe of interpretation for the evaluation process, and which, in the default case, is the real world (or rather, the evaluator’s interpretation of it [...]).”

The most influential cognitive linguistics conception of epistemic modality has conceived of it as a metaphorical projection of forces from the socio-physical into the epistemic realm (cf. Sweetser 1990). In definitions of epistemic modality in terms of a mapping of forces, the notion of evidence becomes part of the definition, thus making obvious the relatedness of the two concepts, but at the same time also the problems involved; in the epistemic domain, the only imaginable ‘force’ can be the ‘force of evidence’ (in the form of premises), which would, for instance in the case of epistemic *must*, compel the speaker to conclude that *p*. But the force of evidence is also present in the other epistemic modals, such as *may* and *might*—the only difference between them perhaps being that the conclusion is stronger or weaker. It can likewise be shown that the schematic structure of the source domain is not invariantly mapped onto the target domain; there are above all differences in the attention patterns involved in the mapping.³⁰ For the objective of the present article we may disregard the categorization problems involved in the potential mapping of forces from the non-epistemic to the epistemic domain and move on to the potential distinction or conflation of the two categories of evidentiality and epistemic modality.

A very straightforward distinction between evidentiality and epistemic modality has been suggested by De Haan³¹—it has meanwhile acquired a slogan-like status among the specialists: While evidentiality is seen to assert the evidence (recall: this only requires the that-version of evidentiality, not necessarily the which-version), epistemic modality is supposed to evaluate the evidence (in terms of different degrees of epistemic certainty). While evidentiality is, as has been shown, generally structured as a collection of discrete types, epistemic modality is usually considered gradable in terms of degrees of certainty. On the

²⁹ Though the term ‘commitment’ has turned out to be problematic as well; see, e.g., Nuyts’ distinction between performative and descriptive uses of modal expressions: “A performative expression marks an attitude [i.e., an evaluation of a proposition, G. Lampert] to which the speaker is fully committed at the moment of speech. In a descriptive use, the speaker is not committed, but is only reporting on an attitude regarding some state of affairs held by someone else, or by the speaker at some point in time other than the moment of speech, or as a hypothetical possibility.” (Nuyts 2006: 15).

³⁰ More details on problematic issues have already been discussed in Günther Lampert and Martina Lampert (2000: 232–233).

³¹ See, e.g., De Haan (2005: 380).

other hand, there is such a notion like ‘evidentiary strength’, which also appears to be gradient: something can indeed be more or less obvious/apparent/evident—but still, it remains an open question whether this entails a stronger or weaker commitment to the factuality of the stated proposition. Occasionally, attempts have been made to correlate evidentiary strength with the type of evidence: direct evidence would then be rated higher, and mediated evidence lower. Yet, the correlation does not hold across the board; it is, as Nuyts (2005, 2006) observes, in fact cancellable: if the reported evidence comes from an expert, it will of course be rated higher than a potentially fallible piece of sensory direct evidence obtained by the speaker. Given the fact that evidentiality and epistemic modality are closely related and thus not easily disentangled, it comes as no surprise that the relatedness of the two categories has been described in various mutually exclusive ways³²:

- There is the view, prevalent now in the specialist literature on evidentiality, that evidentiality and epistemic modality must be seen as conceptually disjoined.
- One strong minority view³³ holds that evidentiality should be a subcategory of epistemic modality (or epistemicity).
- Then there is a second minority view that includes epistemic modality in the category of evidentiality (see Papafragou 2000 and Infantidou 2001); so here evidentiality would be the superordinate, and epistemic modality the subordinate category.
- Next, the idea of a conceptual overlap has likewise been entertained—for instance in the semantic map approach by Van der Auwera and Plungian (1998: 85-86).
- An interesting suggestion that goes beyond these set-theoretically oriented and discrete classifications has recently been made in Wiemer (2008: 9); he sees evidentiality and epistemic modality tied up in a mutual implicational relationship that can be characterized in terms of a figure-ground contrast. Depending on the environment, the situation, and, moreover, on diachronic tendencies, one or the other ‘meaning’ can move into the foreground, while the other will then recede into the background (but never totally disappear, it seems); *seem* may thus once become, for instance, a hearsay marker, and, next time, a marker of epistemic (un-)certainty.

Importantly, though, in many accounts, no principled distinction is being made between the conceptual and the formal levels of linguistic signs; they are (often tacitly) conflated.

4. A CASE STUDY ON *SEEM*

4.1. Syncretism in the Expression Domain: *Seem* as an Epistential

Siding with the majority view this time, the position of the present article is that evidentiality and epistemic modality should, in the conceptual domain, be kept apart, but that a large extent of syncretism is to be expected in the expression domain. This insight has motivated the introduction of a new term: Faller (2002: 87) for the first time refers to verbs

³² For more detailed accounts cf. Cornillie (2007); Wiemer (2008); Boye (2011).

³³ This is actually the initial view, dating from the first symposium on evidentiality; see Chafe and Nichols (eds.) (1986).

that characteristically display such syncretism as epistentials: “Let us call an element that expresses evidentiality and epistemic modality simultaneously provisionally epistential.”

Perhaps the typical epistential in English is the key item of the present article, the verb *seem*, although it must be stated that the evidential and, concomitantly, the epistemic meanings of *seem* are generally taken as given, but hardly ever argued out. The clearest statement to the effect that an equivalent of *seem*, the German verb *scheinen*, is both an evidential and an epistemic marker can probably be found in Diewald and Smirnova (2010a: 2-3); referring to a potential utterance *Sie scheint ihren Schirm im Büro gelassen zu haben* ‘She seems to have left her umbrella in the office’, and after characterizing *scheinen zu* beforehand as a “typical evidential expression” (2), the two authors state:

“In this example the evidential construction refers to the fact that the speaker derives his/her conclusion from some (visual) evidence she/he has for making the claim (namely ‘She has left her umbrella in the office’). The undeniable fact that this sentence also refers to the uncertainty of the speaker, implying that she/he does not have secure knowledge, is due to a particular trait of German evidentials, namely the fact that German evidentials very often have epistemic modality meanings as a concomitant feature.” (2-3)

Even if the word *fact* is used three times in the quote, it cannot obscure the ‘fact’ that what we read here are just claims not backed up by any supportive evidence. Do we really know from the utterance quoted that, as Diewald and Smirnova write, the speaker draws his/her evidence from some “visual evidence”? Do we really know that the “uncertainty of the speaker” is an “undeniable fact”? And, finally, how can we know the “fact” that German evidentials have epistemic modality meanings as “concomitant features” (of what type)?

If this was just an isolated interpretation, or a kind of shorthand notation, it could easily be glossed over, but, unfortunately, it is quite typical of old and new research on *seem* (and, no less, on *seem*-constructions). In the case of Diewald, she has in fact been propagating for more than a decade now (beginning with Diewald 2000, continuing in 2001 and 2004) that German *scheinen* (and, by virtue of the translations given, its English counterpart *seem*) encodes an uncertain factivity value *and* an unspecific evidential component³⁴. What has changed in her account over time, however, is a matter of semantic ‘primacy’; while in her earlier accounts, evidentiality and epistemic modality were seen on a par, or even the epistemic meaning to be more salient, Diewald and Smirnova (2010a, b) now claim that the evidential meaning of *scheinen* is primary, and that any epistemic modal value must be treated as a concomitant, or as an implicature³⁵.

While older studies like Bäcklund (1982) turn out to have been more interested in the lexical semantics of *seem* (to distinguish it from a more ‘factual’ *appear*), the most recent accounts do not have the lexical meaning of *seem* (or its equivalents in other languages) in their focus, but rather unanimously concentrate on the various *seem*-constructions and tend to read or project their meanings into the lexical meaning.³⁶ In the literature on English *seem*-constructions, the following constructional variants are commonly distinguished:

³⁴ See Diewald (2001: 91).

³⁵ Cf. Diewald and Smirnova (2010a: 93) and (2010b: 126).

³⁶ See, for English, Gisborne and Holmes (2007); De Haan (2007); and Aijmer (2009); for Spanish Cornillie (2007a, b); and for German Diewald and Smirnova (2010a, b).

(a) *seem* + infinitival predicative complement (the subject-to-subject raising construction): *He seems to be tired*

This construction is generally considered to be the most grammaticized type of seem-constructions³⁷, especially in combination with other verbs than *to be*.

(b) with a clausal subject: *that he is tired seems to be too obvious*

In my view, this is just a positional variant that affects the attentional values of its components, but does not yield any new semantics.

(c) *it seems* + *that*-complement clause: *It seems that he is tired*

(d) as (c) + subjective 'experiencer': *It seems to me that he is tired*

Of course, this is a more 'subjective' variant of (c), because it makes the experiencer overt.

(e) comparison clause: *It seems as if/as though he is tired*

(f) *seems* + adjectival predicative complement: *He seems tired*

(g) as (f) + subjective experiencer: *To me, he seems tired*

(h) as a parenthetical: *He is tired, it seems / It seems, he is tired*

To these, yet another construction might be added that, if one can trust *OED* evidence, in fact yields the first recorded truly evidential sense of *to appear*. It is found in Shakespeare's *The Merry Wives of Windsor* (III.i.72), and it mentions the perceptual source of information in the immediate linguistic environment:

(2) *Page*. Hee's the man should fight with him.
Shal. It appears so by his weapons.

The construction can be used with *seem* as well, and it is indeed attested today in Web examples in the form of *it seems so by/according to*—though it is not found in *COCA*:

(3) *Maybe it's because I'm American and we produce most pop music, or at least it seems so by what's played on the radio here.*

(4) *Maybe shoving is something taught in police school in Arizona? It seems so by the looks of this video, where a 15-year-old girl is slammed to the ground by Phoenix Police Officer Patrick Larrison.*

(5) *Crow pose the new cure for midlife crisis? [a yoga pose] It seems so, according to the New York Times. This week's Sunday Magazine purports that women are now responding differently to midlife crises than they first did with the rise of feminism in the '70s.*

What makes this construction noteworthy is the observation that, unlike in the preceding ones, the purported evidence is mentioned next to *seem*. But even here, the problem of what *seem* does contribute to the meaning of the utterance is not yet solved.³⁸

It turns out to be the case that in the construction-based approach there is an obvious predilection for holistic over distributed semantics conceptions (cf. Sinha and Kuteva 1995): elements of context are thus regularly projected into the semantics of a lexical item—a

³⁷ This unites the studies mentioned in the preceding footnote.

³⁸ From a constructional point of view, another very interesting construction might be the *can't seem to*-construction; cf. Jacobson (2006) for a recent analysis (which has, however, its problems also).

strategy that, in my view, is the main reason why the number of the stipulated senses then tends to explode.

The problem of how to control the number of senses a lexical item is assumed to have has in fact been a long-standing one in cognitive linguistics descriptions of the semantics of lexical items (actually since the first over-studies by Lakoff and Brugman appeared in the late 1980s), and it has since then been the source of many debates. Even if I do not intend to engage in the matter in any detail, I need to state that it still is an unresolved issue. This can be gathered, for instance, from Gregory L. Murphy's (2011: 393-395) review of Evans (2009), where he points out the dilemma with regard to the semantics of the verb *fly*.

(6) *The pilot is flying the plane.* [operation of entity capable of aerodynamic motion]

(7) *The child is flying the kite.* [control of lightweight entity]

To be able to follow his line of argument, I will quote Murphy in full:

“Why does E assume that the meaning differences are associated with the word *flying*? Could it not be that this verb is contributing the same meaning but its arguments are modifying the meaning? If there is a semantic difference between (6) and (7), it would seem to be the difference between planes and kites, not in flying. Even if there is a different semantic contribution from *flying* in the two cases, why does this amount to a difference in senses? The book merely stipulates that these are two different senses, rather than explaining or arguing for this difference. E's assumption seems to be that any difference that he can identify in such sentences means that there is a difference in sentence meaning and therefore lexical meaning. The well-known problem with this approach is that it results in each word having far more senses than anyone wants or believes. Indeed, every word will become massively polysemous by this account. For example, why not posit that words like *neighbor* or *boss* have two senses, one for each gender?

After all, (8) only makes sense with a male and (9) with a female.

(8) *My neighbor married his third wife.*

(9) *My boss is pregnant with triplets.*

With little effort, we could produce examples that make sense only with tall neighbors or neighbors who do not speak English as their native language or rude neighbors, and so on. Instead of positing all of these forms of polysemy, it is usual to say that the word is GENERAL with respect to gender, height, rudeness, and so on (...). That is, these variables are omitted from the lexical entry, and *neighbor* can be used irrespective of their values. Why not say that *flying* is general with respect to the type of object being flown? Would that account for all the data? This possibility is not addressed.”

My own position of the matter has decisively been influenced by Talmy's views, especially by his conviction that the meaning of morphemes and of constructions should be kept apart (if only for heuristic purposes), and that even when the generalized semantics of constructions is at issue, the core meaning of morphemes must not be overlooked (cf. Talmy, forthcoming).

What could be yet another (unexpected) counter-argument against the construction-based view of *seem* and its ‘rich’ semantics is the finding that, at least for English *seem*, we cannot reconstruct any grammaticalization paths or any order of occurrence of the different constructions.³⁹ All the relevant *seem*-constructions are available almost simultaneously in the 14th century (if the *OED* attestations can serve as trustworthy evidence; see also Gisborne and Holmes 2007).⁴⁰

In contradistinction to what the hegemonic constructional accounts claim, I hold that none of the constructions mentioned above will yield any significant bias toward one specific evidential reading. If evidence is given for the stated proposition modified by *seem* at all—and this is very often not the case—it is usually found in the wider context, not in the immediate environment of the *seem*-construction itself. And, likewise, the degree of certainty that may be associated with any proposition that is modified by *seem* is entirely context-dependent and cannot be predicted from the construction type alone. Although a close inspection of a large random (contextualized) sample of the 236,618 word forms of the *seem* lemma in the most recent version of *COCA* (as of August 29, 2011) cannot be conclusive evidence—because in fact all occurrences would have to be checked—the six-line context provided in *COCA* is rarely sufficient to trace the mode or the source of evidence.

So, even under the auspices of the construction approach, the fundamental categorization dilemma (also voiced in Aijmer 2009) cannot be explained away: Is *seem* evidential or epistemic or both? And if this problem lingers on so tenaciously, why not look for an alternative and dare to ask the question: Maybe it is neither? Or, to reformulate this question into some research agenda, perhaps another framework can be found in which it may become possible to arrive at a more satisfying description of the meaning of *seem*.

To back up my strategy of finding a way out of the categorization deadlock, I will first present some findings about actual co-occurrence patterns of *seem* that can shed light on the intricate relationship between evidentiality and epistemic modality in the semantics of *seem*.

4.2. Co-Occurrence Patterns of *Seem*

First of all, one has to note that *seem* (in different construction types) can co-occur with prototypical evidential adverbs, as in the following examples (excerpted from *COCA*):

- (10) *The monthly fees sound low, and for millions of users they evidently seem so ...*
- (11) *and their mother, who obviously seems to be siding with one sister ...*
- (12) *Even now, Baghdad apparently seems quite disappointed ...*
- (13) *As an overzealous Los Angeles police officer, Samuel L. Jackson clearly seems ready to head down such a clichéd, schlocky road ...*

If the primary meaning of *seem* is evidential, as Diewald and Smirnova (2010a, b) claim it is, we would, in examples (10) – (13) at least, have evidentiality marked twice. If this were

³⁹ Cf. De Haan (2007), and *pace* Gisborne and Holmes (2007).

⁴⁰ Though this article is not concerned with *appear*, it should be noted that the situation is different there. In the case of *appear* we observe clear instances of semantic bleaching, with subjects being taken from increasingly abstract ontological classes; clausal subjects apparently allow evidential meanings, and subject-to-subject raising is seen to follow this development.

so, what would then be the difference in function between the evidential adverb and *seem*? It cannot be that the adverb contributes information about the mode or the source since both expressions are quite unspecific in these respects: they just state that there is some evidence. One could possibly argue that one expression makes the statement more intersubjectively valid—but, again: which of the two would it be?

An obvious way out might be to consider *seem* not an evidential but rather an epistemic marker—but how should we now cope with the fact that *seem* can also co-occur with central adverbial markers of epistemic certainty?

(14) *And would you actually repeat words like these—even if you want them to be true? It probably all seems a little silly or superstitious, to say nothing of embarrassing.*

(15) *They sure seem to be able to do some things right ...*

(16) *Joe Biden certainly seems to be enjoying himself ...*

(17) *That doesn't necessarily seem to be the case ...*

(18) *Mary truly seems to enjoy the place ...*

In case *seem* should primarily associate an epistemic value such as 'considered probable', we would run into yet another problem, namely that the epistemic value of the adverbial marker would then just reinforce the epistemic value of *seem*. Only if *seem* were an evidential marker (and had no epistemic values attached to it), the adverbial epistemic marker could be analyzed as evaluating the evidence that *seem* only states it exists. Then, however, we would be faced with the problem discussed just a while ago, and our argumentation would have come full circle: sometimes *seem* would be an evidential marker, sometimes an epistemic marker—but we cannot know when unless there is something that triggers its more salient reading (this is what Wiemer (2008) would seem to suggest).

To round off this account, it needs to be mentioned that *seem* can also co-occur with markers of epistemic possibility (or uncertainty):

(19) *Archaeology perhaps seems 'old' because we associate early civilizations ...*

(20) *Which is why maybe he seems so composed ...*

And, to conclude, we likewise observe a combination of *seem* with modal verbs of certainty and possibility:

(21) *It must seem pretty comical to hear me coming down on the side of stricter editing*

(22) *As strange as it may seem OR Strange as it may seem*

Again, we would have to deal with the problem that, this time, an epistemic value of (un-)certainty would be reinforced by yet another marker of (un-)certainty. So, all one can state is that, for the time being at least, the problem of assigning a meaning to *seem* that would involve evidentiality and/or epistemics has not been solved.

To avoid a renewed confrontation with these problems I will therefore suggest a way out by accessing semantic constructs from Talmy's cognitive semantics.

4.3. A ‘New’ Semantics for *Seem*: Fictivity/Factivity, Figure/Ground, and the Comparison Frame

While so far the pertinent domains of meaning evoked by *seem* have been modes and sources of evidence, degrees of certainty, and (inter-)subjectivity, I will now focus on the opposition between factivity/veridicality vs. fictivity/non-veridicality that I have touched upon in the introduction, and I will claim that it is crucial for an adequate description of the meaning of *all seem*-constructions.

The factivity vs. fictivity dichotomy was first treated in Talmy’s fictive motion article from 1996⁴¹ where the two concepts are seen to associate a major cognitive pattern involving a discrepancy within the cognition of a single individual of two different cognitive representations of the same entity—for instance a situation or an event. One of the two representations is assessed as more veridical than the other; there need not be a conflict or a clash between the two representations, because they may be seen as alternative perspectives. Of the two discrepant representations, the one assessed as more veridical is called *factive*, the one assessed as less veridical is referred to as *fictive*. It must be emphasized that the two terms are meant to represent cognitive assessments: *factive* (not: *factual*!) is not to suggest that the representation is in any sense objectively true or real; *fictive* refers to the imaginal capacity of cognition—it does not signal ‘objectively unreal’ or ‘not true’.

When, in a next step, the notions of factivity vs. fictivity are linked up with another cognitive construct (introduced by Talmy in his 1996 windowing article⁴²), the comparison frame, a more adequate description of what *seem* might mean will ensue. Some explanatory remarks are in order: the comparison frame is considered a subtype of one of the basic event-frames reconstructed in that article, the so-called interrelationship event-frame:

“a conceptual complex that contains or is comprised of parts not autonomous in themselves but intrinsically relative with respect to each other, where the presence of one such part necessarily entails the presence of the other parts. A conceptual complex of this sort is here called an interrelationship complex and can constitute a further type of event-frame, the interrelationship event-frame. Such an internally self-entailing complex could logically be considered a single-unit entity, but our conceptual and attentional systems are so organized as to be able to conceptualize the whole as if portioned out into quasi-independent elements to which heightened attention can be differentially directed.” (Talmy 2000.1: 288)

One subtype of this interrelationship event-frame is the factuality event-frame, one subtype of which is the comparison frame. Here the placement of the two alternative or discrepant conceptualizations can be accomplished within a single frame of consideration,

“so that although main attention is on only one of the alternatives, the other alternative is still present in a backgrounded way to act as foil for comparison. An event frame that in this way evokes larger-frame juxtapositions of alternative conceptualizations can be further said to constitute a comparison frame.” (Talmy 2000.1: 291)

⁴¹ The most recent version is Talmy (2000.1); see especially 99-100.

⁴² Cf. the latest version in Talmy (2000.1); see especially 288-292.

If we apply the notion of the comparison frame to the fictivity system and link this up with the attention system, we will encounter an example of how language may recruit several cognitive systems to integrate (see Talmy 2011).

To illustrate how the comparison frame can be implemented, I will briefly refer to Talmy's analysis of a syntactically negative clause like, say, *I didn't go to John's party last night*. This clause, Talmy emphasizes, "overtly names something that did not take place but tends to evoke consideration of the corresponding unrealized positive event—and in this respect it differs from a simple positive clause, which tends not to evoke consideration of its negative counterpart." (Talmy 2000.1: 291) The second of Talmy's examples refers to a syntactically positive main clause when it is combined with a *because*-clause (e.g., to cite Talmy: *I went to the movies last night because they were playing my favorite film*). In this case the complex sentence "tends to evoke its unrealized counterpart (a failure to go to the movies) since the inclusion of a reason or cause that has given rise to some realized phenomenon suggests that, in the absence of that cause, the phenomenon would not have occurred." (Talmy 2000.1: 291) And, to end up with yet another example, which concerns epistemic *may* and is thus semantically close to the *seem*-case that I will discuss immediately: *Sue may have gone to John's party last night*. Following Talmy, *may* "includes a constituent placing the referent event at some point along a scale of certainty or realizedness" (Talmy 2000.1: 292); it yields the existence of such a scale and "thereby evokes the consideration of points nearer the opposite pole of the scale" (Talmy 2000.1: 292).

Equipped with the concepts of the comparison frame and the opposition of fictivity vs. factivity, I can now construct the core meaning of *seem* as oscillating between factivity and fictivity within one single comparison frame, where main attention is on one of the alternatives, say, fictivity, but where the alternative, factivity, is co-entailed and thus still present in a backgrounded way, "to act as foil for comparison", to use Talmy's wording.

Constructed in this vein, the core meaning of *seem*, which I claim holds for all *seem*-constructions, draws upon yet another well-known fundamental perceptual opposition, that of figure and ground. Figure/ground organization was discovered by the Danish psychologist Edgar Rubin in 1921⁴³ and covers an aspect of region segmentation in visual displays where one partitioned out segment is subjectively perceived as thing-like, closer to the observer, bounded by contours (in stationary displays), or as moving (in moving displays), while the other is perceived as not thing-like, farther from the observer, extending behind the contour, and stationary. The first type of segment is called the *figure*, the backgrounded one the *ground*. Sometimes, however, such visual displays tend to become highly ambiguous (the most famous example would be the Rubin vase); so other (bottom-up or top-down) factors will be needed to determine what is figure and what is ground. Applying this vision-related constellation to the construct of the comparison frame in language, which is here supposed to account for the semantics of *seem*, we may observe that the segmentation of the semantic space into a fictive and a factive 'segment' tends to be likewise ambiguous. The principles of what may eventually determine figure detection in vision are, according to Palmer (1999: 282) *ceteris paribus* rules—"rules in which a given factor has a stated effect if all other factors are eliminated or neutralized". Yet the problem immediately emerges that the eight factors mentioned by Palmer (surroundedness, size, orientation, contrast, symmetry,

⁴³ The following is mainly based on Palmer (1999: 280-285).

convexity, parallelism) usually do not occur in isolation; hence, it seems impossible to predict the perceptual outcome if several conflicting factors are at work in a display.

Pushing the analogy of figure/ground organization in vision and in language a bit further, one would then have to ask what could correspond to Palmer's vision-related factors; that is, which factors might be responsible for favoring one reading in the present systemically ambiguous factive/fictive configuration (the *seem*-semantics). If in vision such factors relate to the ecology of the configuration in question (or maybe to deliberate decisions of the observer)—in language they may, accordingly, be found in the ecology, that is, in the linguistic or non-linguistic environment of the ambiguous item in question.

4.4. Tipping the Balance: Non-Dedicated Lexical Triggering

While *seem* has been conceived of as generally evoking a comparison frame with a juxtaposed fictivity/factivity configuration, linguistic items in the immediate environment (at least in English) can select one of the two readings to make it the figure, and the alternative the ground.

To detail how this might be accomplished, I need to describe some co-occurrence patterns again. In the immediate linguistic environment of *seem* we frequently find focusing adverbs whose function it may be to draw hearers'/readers' attention to what will be perceived as the figure in a textual constellation that can be viewed as corresponding to a visual display.

To trigger⁴⁴ the factivity reading, adverbs such as *really*, *just* or *clearly* may be selected:

(23) *It really seems like he is more conservative ...*

(24) *It just seems like the whole world is spinning out of control ...*

(25) *the mood of the world at large clearly seems to be all but unanimous that Iraq was the aggressor ...*

(26) *Here, indeed, we are up against what truly seems like the obsolescence of serious art in general ...*

The juxtaposed alternative fictive reading of *seem* can be triggered by adverbs such as *only* or *merely* (note that the selection is accompanied by a special stress pattern, with *seem* becoming attentionally more salient because of heightened stress):

(27) *The image only 'seemed to burn brighter ...*

(28) *It merely 'seems unlikely ...*

Reverting to the question that stood at the beginning of section 4, "Where does evidentiality reside?", I now conclude that *seem*'s lexical semantics does not readily license the verb as an evidential marker. Both the relevant mode of evidence and its associated degree of (un-)certainty are entirely matters of context, and never part of the core meaning of *seem*. This assumption may be plausible since, as has been shown, linguistic items are available to

⁴⁴ To interpret these adverbs as a form of (non-dedicated) triggers to select out a targeted reading of a polysemous lexical item has again been inspired by Leonard Talmy's ongoing work on the attention system in language.

trigger, if necessary, one of the two alternative readings of factive or fictive *seem*, making the selected reading contextually more salient than its competitor, which is, however, still attentionally present, though in a backgrounded way.

4.5. Two Extended Examples

To contextualize my attempt at capturing the semantics of *seem*, I will, next, analyze two extended examples in somewhat more detail. Here is the first one:

(29) *Archaeology perhaps **seems** “old” because we associate it with early civilizations (which we need not do), but in fact rigorous archaeology is very modern indeed.*

In this example, the *because*-clause provides the necessary contextual evidence for a potential claim ‘archaeology is old’. This categorical assertion is, however, immediately mitigated by the speaker’s comment that is inserted within the parentheses. Though that comment is, according to the still dominant view of parenthetical constructions (for convincing counter-arguments see, however, Martina Lampert, forthcoming), supposed to be informationally less salient than its host, it nevertheless triggers the fictive reading of *seem*. This fictive reading of *seem* is, in a next step, additionally motivated by the inclusion of *perhaps* (with its associated low degree of epistemic certainty). And, finally, the added *but*-clause contains yet more support for the intended fictivity reading, namely by virtue of the selected syntactic form, a categorical assertion, and the booster *in fact*. Thus, all in all, we find four triggers that are used here to disclose the stated proposition ‘archaeology is old’ as a dubious assumption, and the potential reason for this assumption adduced in the *because*-clause as a pseudo-argument. Yet despite all the triggering devices he adduces, the author still did not wish to make a negated statement of the form *Archaeology is not old, even if or despite ...* Instead, she or he preferred to choose a *seem*-construction—maybe because, I would suggest, using *seem* always provides interlocutors with the (strategic) option to cancel the salient reading by later adducing a statement of the sort *I only said ‘seemed’, but didn’t mean it is*.

If in the first example we could observe various triggers that make the fictivity reading of *seem* more salient (i.e., figural), in the second example it is the alternative factivity reading that is moved into the foreground of readers’ attention.

(30) *And with this story of a psycho-cop who tries to run off his new next-door neighbors, you wish he’d have just given into the B-movie instincts of the material, and not tried to make “Lakeview Terrace” about Something Important. As an overzealous Los Angeles police officer, Samuel L. Jackson clearly **seems** ready to head down such a cliched, schlocky road. He is, after all, the one who triumphed over all those (expletive) snakes on that (expletive) plane.*

In this example, we find the ‘evidence’ for the stated proposition in the immediate linguistic environment. The intended ‘factive’ reading of *seems* is here triggered by *clearly*, which adds some extra epistemic strength to the veridicality of the proposition affected by *seems*. But here, too, the writer refrains from uttering an unmodified ... *clearly is ready*.

So it has turned out that, like in vision, “attention cannot be completely determined by figure/ground organization” (Palmer 1999: 284). If it were so, the ground could not be attended to—but we know that it can. If this insight is transferred to what may happen in language use, top-down decisions of the hearer/reader may always override the triggered reading; and so the following quote from Palmer (1999: 284) can likewise be read as an apt summary of the corresponding situation in language: “It thus seems clear that attention can be flexibly allocated to either figure or ground, depending on the goals and intentions of the observer, but that there is a strong bias to attend to figures.”

As to *seem* and its core semantics, it is systemically ambiguous between a fictive and a factive assessment of the situation (this is the function of the juxtaposition within the comparison frame); this ambiguity can be overcome by (optional) non-dedicated triggers, but the ultimate reading of *seem* depends on hearers’/readers’ attentional top-down decisions.

5. SUMMING-UP: A LINE OF REASONING

After sorting out what I take to be the core meaning of *seem*, I can now briefly sum up my line of reasoning and draw some conclusions. *Seem* is, I propose, neither an unequivocal lexical marker of evidentiality (not even in the sense *that* there is some evidence, let alone in the sense that it specifies the mode or source of evidence), nor is it an epistemic marker that would evaluate the assertion in terms of a fixed degree of epistemic certainty. Rather, by adopting the cognitive semantics framework, we can understand *seem* as evoking a factivity/fictivity comparison frame: a juxtaposition of alternative conceptualizations within a single frame with an ambiguous figure-ground distribution. This is *seem*’s (highly schematic) core semantics, which may get augmented by optional non-dedicated lexical triggers (like epistemic or evidential adverbs or other modal expressions) that are conducive to biasing the interpretation either way (though not completely determining it). By conceptualizing the meaning of *seem* in this way, the notorious problem of the double marking of evidentiality or epistemic modality dissolves.

And, theory-internally, my study may be read as a plea for more investigations of how schematic systems can be recruited to integrate. The systems that I have addressed in the present attempt at capturing the semantics of *seem* as a member category of the schematic system of cognitive state are the fictivity system, (pre-attentive) figure/ground organization, and the attention system (with both its bottom-up and top-down components). These systems’ interaction provides this sub-system of cognitive state with a conceptual structure of which *seem*, and *appear*, for that matter, become important instantiations: *Seem*, as has been suggested already in my ‘Shakespearean’ introduction, is to be located in a semantic space where its two natural counterparts turn out to be *is* and *is not*—it thus becomes a further member of what Talmy names the factivity subsystem of cognitive state.

Chapter 77

MANNER OF MOTION: A PRIVILEGED DIMENSION OF GERMAN EXPRESSIONS

Sabine De Knop¹ and Françoise Gallez^{1,2}

Institut Libre Marie Haps, Brussels, Belgium

ABSTRACT

Within Talmy's (2000) and Slobin's (1996) typological framework, German belongs to satellite-framed languages, which generally express the path of motion in satellites and the manner of motion in the main verb. For Talmy (2000: 281), the expression of the path is the most basic information, it constitutes the core component; the manner expression is a subsidiary dimension.

Many studies have focussed on the typological differences between different languages based on the path expression and have paid less attention to the expression of the manner dimension.

Our study aims at taking a closer look at this neglected dimension of the manner of motion as it is realized in German. It will show that German is characterized by a manner salience which is realized at different levels of lexicalization and which is not restricted to motion and location verbs as the core of the lexicalization pattern.

The manner of motion is typically also expressed in complex prepositional groups, especially with the preposition *bis* ('up to/till/until'), or at the level of complex local adverbs or postpositions which are hardly translatable into other languages. Constructions with complex particle verbs which combine a particle expressing a path of motion with a simplex verb that expresses a manner (but not a motion), constructions with a non-motion manner verb accompanied by a path satellite, or syntactic structures that combine a modal verb with a path satellite are typical for the German language as they combine in one structure expressions of path and manner of motion.

The study presents the theoretical aspects of these different categories highlighting the «German way of thinking and speaking».

It further illustrates the difficulties encountered when trying to translate the above examples into the verb-framed language French, which often omits the expression of manner.

Keywords: typology, satellite-framed languages, verb-framed languages, path of motion, manner of motion, German

1. INTRODUCTION

Since Talmy's (1985, 2000) and Slobin's (1996, 2000) seminal works about the typological differences in the expression of motion and location in different languages, it is well-known that Romance languages belong to the category of verb-framed languages, whereas Germanic languages are characterized as being satellite-framed languages. This terminology finds its motivation in the lexicalization preferences for the expression of motion events in each typological group. Romance languages, e.g., French or Spanish, express the path of motion in the main verb, whereas Germanic languages like Dutch or German favour a so-called 'satellite' (see Talmy 2000 for the terminology) for the expression of a path or a trajectory. Compare the following underlined elements in the French and German examples (1) and (2).

(1) *Elle entra dans la cuisine, traversa la salle à manger, pour sortir de la maison.*

Lit. 'She entered the kitchen, crossed the living-room, to exit the house.'

(2) *Sie trat in die Küche hinein, lief durch das Wohnzimmer durch, um aus dem Haus zu rennen.*

Lit. 'She walked into the kitchen, ran through the living-room (through), to run out of the house'.

In example (1) French selects three main verbs for the expression of the motion path, whereas German (example (2)) uses prepositions or particles to express the same path. Additionally, Germanic languages express the manner of motion in the main verb (e.g., in example (2): *trat*, *lief* or *rennen*). This dimension is not so relevant in Romance languages and consequently is often not expressed in these languages or alternatively is expressed with a gerund or an adverb.

Many studies have focussed on the typological differences between different languages. If we simply consider comparative studies of Romance languages with Germanic languages we can quote among others, Berthele (2004), (2006) and Hottenroth (2002) for a comparison of French and German, Pourcel and Kopecka (2005) for a comparative study of French and English, Lemmens and Perrez (2010) for Dutch as compared with French or De Knop and Perrez (under review) for a comparison of Dutch, German and French expressions of motion events. The studies by Lemmens and Perrez (2010) and by De Knop and Perrez (under review) further deal with the typologically motivated difficulties encountered by foreign language learners. It is interesting to observe that most studies pay less attention to the expression of the manner dimension (except for a few isolated studies, e.g., Pourcel (2009) for English as compared with French). This can probably be explained by the following assumptions:

- Talmy (2000: 281) claims that the expression of the path is the most basic information, it constitutes the core component; the manner expression on the other hand is a subsidiary dimension.
- The differentiation between satellite-framed and verb-framed languages is based on the expression of the path.
- The manner dimension is not so relevant for speakers of Romance languages as it is often not expressed. In his contrastive study of translations of English sentences into the Romance language Spanish Slobin (2000) has shown that the manner expression is often missing which makes it further understandable why a description of this dimension is less attractive.
- The study by Pourcel (2009) aims at assessing which variable between path and manner is cognitively more salient to subjects. She provides evidence (2009: 385) for the fact that speakers of a Romance language, e.g., French, recall better the expression of path, whereas English speakers as representatives of a Germanic language better remember the expression of manner.

Our study aims at taking a closer look at this neglected dimension of the manner of motion as it is realized in German. It will show that German is characterized by a manner salience. The following section 2 will describe the different levels at which the manner of motion is realized in German. It will become obvious that the manner salience is not restricted to motion verbs as the core of the lexicalization pattern but that it pervades several levels in the German language. In section 3 we will illustrate the difficulties encountered by French-speaking students with the German expressions of manner of motion, thereby showing that many problems have something to do with the «German way of thinking and speaking» (Slobin 1996). Finally, section 4 will draw the conclusions and present the results of the study.

2. REALIZATION OF THE MANNER DIMENSION IN GERMAN

Talmy (1985 and 2000) and Slobin (1996 and 2000) concentrated their study of the expression of motion events on the lexicalization patterns realized by motion verbs and satellites. We will show in this section that the manner dimension is not only expressed at the level of motion or location verbs in German but that it pervades several levels of lexicalization. In the following we will offer a systematic overview of all the realization possibilities of the manner dimension in German. Let us start with simplex verbs.

2.1. Simplex Motion Verbs

German as a Germanic language expresses motion in a very differentiated way as it uses different motion verbs to express the way individuals are changing places or objects are being moved (see De Knop and Dirven 2008). Languages from a different typological category, e.g., Romance languages like French or Spanish, also have several motion verbs but these verbs are used very differently. In the German motion and posture expression there is an

obligation to specify the manner of motion, which does not pertain to French (or even the Germanic language English). So consequently, the German speaker will alternatively use the verbs *fahren* ('to drive with a boat, car, ship'), *gehen* ('to go on foot'), *fliegen* ('to fly'), *stellen* ('to put in an upright position'), *setzen* ('to put in a sitting position') or *legen* ('to lay'), whereas French will rather use very general verbs like *aller* ('to go') or *mettre* ('to put'). If one is living in Europe or America he/she cannot say in German

(3) *Ich gehe nach Peking.* ('I go to Beijing'),

as this would imply that he/she goes on foot.¹

2.2. Simplex Location Verbs

A similar differentiation pertains to the expression of location² in German which focusses on the manner of location which is not the case in e.g., French (see also the studies by Ameka and Levinson (2007) for a comparison of different languages, by Kutscher and Schultze-Berndt (2007) or Serra-Borneto (1996) for a description of German and by Lemmens (2002) and Lemmens and Perrez (2010) for a study of Dutch posture verbs). In German there is an obligation to use different verbs to express the location of human beings, animals or objects, e.g.

(4) *Die Vase steht auf dem Tisch.* Lit. 'The vase is standing on the table'.

(5) *Das Buch liegt auf dem Tisch.* Lit. 'The book is lying on the table'.

French (or even the Germanic language English) on the contrary favours very general verbs, e.g., *être* 'to be' or *se trouver* 'to be found'. Compare the following examples (4') and (5'):

(4') *Le vase est/se trouve sur la table.*

(5') *Le livre est/se trouve sur la table.*

These differences based on simplex verbs are very well-known, they have already been described at great length, that is why we will not go further into the details. Let's now turn to other levels of lexicalization which are much more complex.

2.3. Complex Local Adverbs or Postpositions

Complex local adverbs or postpositions are a favoured expression of the manner dimension in German, they function as satellites. Compare the following examples from the German corpora of the Digitales Wörterbuch der Deutschen Sprache (DWDS) and of the Institut für Deutsche Sprache (IDS) in Mannheim:

¹ Still there is one possibility where such a sentence would be acceptable, but with a different meaning. It would then imply that one is moving to Beijing, to work there for instance.

² Talmy considers location to be motion but in a wider sense (2000: 28).

(6) *Dann kam der Tornado bis auf den See herunter.* (IDS: BRZ07/AUG.)

Lit. 'Then came the tornado up to on the lake downwards.'

(7) *Das Wetter bringt Schnee bis an den See hinunter.* (IDS: A00/MAR.16690)

Lit. 'The weather brings snow up to the lake downwards.'

(8) *Ein herrlicher Wanderweg bis auf den Berg hinauf.*

(www.peterkamin.de/Harz/harz.htm)

Lit. 'A wonderful path up to the mountain upwards.'

The complex local adverbs or postpositions consist of two elements: (i) The first constituent is a particle expressing the vantage point (Langacker 1987: 122-126) or the perspective of the speaker, i.e., a (fictive) movement towards the speaker (with *her-*) or away from him/her (with *hin-*). (ii) The second element of the complex local adverb is a preposition which also expresses a path but additionally a manner, e.g., *unter* ('under'), *hinter* ('behind'), *über* ('over'), *an* ('at'), *auf* ('on'), *vor* ('before'),...

Complex local adverbs are favoured in German but hardly translatable into other languages (See De Knop *fc.* 2013), as testified by the awkward English translations above or the corresponding translations into French hereunder:

(6') Lit. 'Alors la tornade vint jusque sur le lac (vers le bas).'

(6'') 'Alors la tornade s'abattit sur le lac.'

(7') Lit. 'Le temps amène de la neige jusqu'au lac (en bas).'

(7'') 'Le temps amène de la neige jusqu'au bord du lac.'

(8') Lit. 'Un chemin merveilleux jusqu'à la montagne (en haut).'

(8'') 'Un chemin merveilleux qui monte jusqu'à la montagne.'

The English translations skip the first part of the complex local adverb, i.e., the vantage point, whereas the French translations have a tendency to skip the local adverbs altogether. If French speakers want to express the local dimension at all they will rather use other lexicalization patterns, i.e., full verbs (example 6''), another nominal group (*au bord* in (7'')) or a relative clause, e.g., *qui monte* in (8'').

German is characterized by a wide variety of possible combinations between the two constituents as illustrated in the following examples:

(9) *Die Häuser reichen bis ans Wasser heran.* (DWDS Kernkorpus)

Lit. 'The houses reach up to the water to at.'

(10) *Getanzt wurde bis in die Morgenstunden hinein.* (IDS: A00/APR.26150)

Lit. 'It was being danced up to the morning hours into.'

(11) *Sie will auf ihn warten bis über den Tod hinaus.* (IDS: A01/AUG.24164)

Lit. 'She wants to wait for him up to over the death over'.

For an overview of the possibilities see De Knop (*fc.* 2013).

2.4. Complex Prepositional Groups with *bis*

Prepositional groups introduced by *bis* ('up to/until') are complex in the sense that the following nominal group after *bis* is often introduced by another preposition³. Let's look at some examples.

(12) *Ich werde dich lieben bis in den Tod.* (DWDS Kernkorpus)

Lit. 'I will love you till into death.'

(13) *Die Wut steht ihm bis über den Kopf.* (DWDS Kernkorpus)

Lit. 'Anger stands till over his head.' = 'is overwhelming him'

(14) *Er arbeitete (spät) bis in die Nacht.* (IDS: I00/DEZ.75273)

Lit. 'He worked (late) till into the night.'

In these complex groups the preposition *bis* expresses the path of motion, either a spatial trajectory, e.g., example (13), a temporal path like in example (14) or a metaphorical trajectory, e.g., example (12). The following preposition often expresses the manner, sometimes also a path. Unlike other languages German is characterized by a great diversity of manner prepositions after *bis* (for an overview see De Knop (2010); compare also Hottenroth (2002)): *bis an die Grenze* ('up to the border'), *bis in die Nacht* ('till into the night'), *bis in den Tod* ('till into death'), *bis über den Kopf* ('up to over the head'), *bis unter das Dach* ('up to under the roof'), *bis hinter den Horizont* ('up to behind the horizon'), *bis zum Gartentor* ('up to the garden gate'), *bis ans Knie* ('up to at the knee'), *bis vor Jahren* ('until before years'),... The selection of the second preposition depends on the noun in the prepositional group whose lexical frame presupposes a built-in scale determining the choice of this preposition. *Bis* evokes the notion of limit exemplified in the so-called 'collocates' (Stefanowitsch/Gries 2003), e.g., *Grenze* ('border'), *Rand* ('side'), *Horizont* ('horizon'), *Tür/Tor* ('door/gate'), but also in body-parts like *Ohren* ('ears') or *Zähne* ('teeth'),... Here too it seems that German offers many possibilities to express the manner of motion which are not really present in French or even English.

Translation difficulties (see e.g., the translations of the above examples) often result from the combination of *bis* which expresses a particular trajectory towards a goal and the second preposition which focusses on a different path, e.g., examples (12) and (13). But they can also depend on the prominence of the manner dimension in German like in example (14).

2.5. Constructions with Complex Particle Verbs

German being a satellite-framed language it favours the expression of the path of motion in satellites, e.g., within constructions featuring complex particle verbs. This explains for instance why a sentence like (a) *Die Kinder laufen rüber (über die Straße)* ('The children go/run over (over the street)') sounds more natural than (b) *Die Kinder überqueren die Straße* ('The children cross the road'). In the first sentence (a) the path is expressed by a satellite,

³ Except for a few examples where *bis* is followed by a noun without article, e.g. *Wir bleiben bis Morgen/kommenden Montag* ('We stay until tomorrow/until next Monday') or *Der Zug fährt bis Paris/Frankreich* ('The train goes/travels till Paris/France').

i.e., *rüber*, whereas in (b) the path is expressed by a full verb (which corresponds to the lexicalization pattern of Romance languages). The satellite in (a) is compounded with a main verb expressing a manner of motion, i.e., *laufen* ('run'). Interestingly, this lexicalization possibility is extended in German to such compounds consisting of a path of motion satellite with a non-motion simplex verb, e.g.,

(15) *Bürgerliche, die in die Kaiserfamilie einheiratete.* (IDS: A09)

Lit. 'Bourgeoise who married into the imperial family.'

One can also 'marry into a country, a region', e.g.

(16) ..., *der vor 36 Jahren nach Waldsassen einheiratete.* (IDS: M05)

Lit. '...who married into Waldsassen 36 years ago.'

Here are some more examples:

(17) *Wer sich so nach oben durchgeboxt hat...* (IDS: BRZ05)

Lit. 'Who has boxed himself through upwards...'

(18) *Michael Schumacher lächelt alle Zweifel weg.* (Berliner Morgenpost, 27.12.2009)

Lit. 'Michael Schumacher smiles all doubts away.'

The non-motion verb often expresses a manner, as illustrated in example (17) or (18). But a simple action, process or state verb which does not as such express a manner is also possible in such constructions, e.g., *heiraten* ('to marry so.') in example (15) or (16), *lachen* ('to laugh') or *arbeiten* ('to work') in the following examples:

(19) *So schön lacht Sylvie van der Vaart (31) den Krebs weg...*

(Bild.de, 14.07.2009 - 19:04)

Lit. 'Sylvie van der Vaart laughs the cancer away in a pretty way'.

(20) *Man muss sich mit dem Auto - teilweise - durch ein Menschengewühl durcharbeiten, so viele Menschen stehen einfach herum.* (IDSSOZ10/JAN.03268)

Lit. 'One must – partly – work oneself through through a crowd of people, so many people simply stand around'.

In order to describe such German examples the whole construction in which these particle verbs are embedded has to be considered. The syntax of the examples can best be studied within the framework of Goldberg's Construction Grammar (1995 and 2006). According to Goldberg the examples under investigation in this paper correspond to 'caused motion constructions'. These consist of several elements:

(i) at the semantic level: of an agent, a patient, a verb and an oblique argument;

(ii) at the syntactic level: of a subject, a direct object, an oblique object and a verb (see Table 1 below).

As Construction Grammar postulates a narrow link or continuum between syntax and lexicon both levels are strongly interrelated and cannot be separated from each other. The

particle contributes to the meaning of the construction, and conversely, any verb associated with a particle in such a construction becomes either transitive or reflexive and can be interpreted as a ‘caused motion verb’.

Table 1. Caused motion construction (Goldberg 1995: 3-4)

Caused motion C°	X causes Y to move Z	Sub	V	Obj	Obl
		<i>Pat</i>	<i>sneezed</i>	<i>the napkin</i>	<i>off the table</i>

The oblique argument which represents the path of motion is expressed by the particle and/or by another satellite (prepositional phrase/adverbial) which can sometimes be redundant with the particle, e.g., (17') *Er hat sich durch die Menschenmenge durchgeboxt*, ‘He fought himself through [verb particle] through [preposition] the crowd of people’. In the case of our examples the separable particle which appears in the compound verb is the oblique argument; the non-motion verb becomes transitive in the particular construction.

The motion expressed with the particle verb is often metaphorical:

- (21) *Du hast etwas (in den Text) hineininterpretiert*. Lit. ‘You have interpreted something into the text.’ = ‘You’ve added a meaning to the text.’
- (22) *Sie konnten das Problem wegdiskutieren*. Lit. ‘They could discuss the problem away.’ = ‘They could eliminate the problem by discussion.’
- (23) *Heute hat sich Lea ins Leben zurückgekämpft* (Welt.de, 16. Februar 2007)
Lit. ‘Today Lea has fought herself back into life.’
- (24) *Die Regierung hat sich bis Oktober durchgelogen*. (Spiegel.de, 21. Oktober 2003)
Lit. ‘The government has lied itself through until October.’ = ‘The government has come through until October by lying.’

For further details see Talmy (2000: 248) and Gallez (in preparation).

Because of the synthetic character of the German compound verbs, which ally in one and the same verb the expression of path with the satellite and the expression of manner in the simplex verb, the translation of such constructions into French is often problematic. In the translations the German satellite particle for the path of motion will be expressed by the main verb in French, the manner of motion will be expressed in French by a gerund or an adverbial, e.g., example (23) here above would be translated into French as ‘Léa est revenue à la vie en se battant’. As the manner of motion is more scarcely expressed in French the translated construction will sound rather unnatural.

2.6. Constructions with Non-Motion Manner Verb + Path Satellite

The following category is close to the preceding one in that the path of motion is also expressed by a satellite and the manner with a simplex non-motion verb, but in the examples of this category the simplex verb and the satellite appear separated in the construction and not as a compound.

Again, the whole construction has to be considered because the different syntactic elements that realize the motion event are spread over several words in the construction. Let's have a look at some examples:

(25) *Die Mutter hat ihren kleinen Sohn in den Schlaf gewiegt.*

Lit. 'The mother has rocked her little son into the sleep.'

(26) *Ein Unbekannter klingelte die Bundeskanzlerin Merkel aus dem Schlaf.*

(http://www.focus.de/politik/deutschland/sicherheitspanne-unbekannter-klingelt-merkel-aus-dem-schlaf_aid_439422.html, 26.09.2009, 16:21)

Lit. 'An unknown (person) rang the chancellor Merkel out of the sleep.'

(27) *Mein Bruder heiratete nach Amerika.* Lit. 'My brother married to America.'

(28) *Colin Firth hat sich im neuen Film «The King's speech» zum Oscar gestottert.*

(<http://www.abendblatt.de/kultur-live/article1799316/Colin-Firth-stottert-sich-zum-Oscar-Portman-brillant.html> 28.02.2011, 10:43 Uhr)

Lit. 'Colin Firth stuttered himself in his new film «The King's speech» to the Oscar.'

The translation of these examples into French is problematic. A translation is sometimes possible and acceptable but it expresses something completely different, e.g., in example (25') or (27'):

(25') Lit. 'La mère a bercé son jeune fils dans le sommeil.'

(27') Lit. 'Mon frère se marie en Amérique.'

In these French translations it is simply expressed that the mother is rocking her young son while he is asleep (25') or that my brother marries in America (27'); the German examples additionally express a path of motion, i.e., that the mother rocks her son until he falls asleep (25)⁴ or that he marries an American woman (27).

This last example is even more intricate as *America* stands metonymically for the American woman the man is going to marry. In order to express this additional meaning of the path of motion French speakers will have to use other patterns which privilege additional full verbs (e.g., *réveilla*, 'woke her up' in (26')) or secondary clauses (*pour qu'il s'endorme* 'so that he falls asleep' in (25')), e.g.,

(25'') 'La mère a bercé son jeune fils pour qu'il s'endorme.'

(26'') 'Un inconnu sonna chez la chancelière Merkel et la réveilla.'

This corresponds to the lexicalization patterns in Romance (as verb-framed) vs. Germanic (as satellite-framed) languages described by Talmy. What is unusual with these examples and therefore problematic for French learners for instance is that the expression of motion is only present at the level of the satellite and not at the level of the simplex verb; the German verb is a non-motion verb that expresses a manner. This is particularly obvious in example (28) which French speakers would probably translate with an additional gerund:

⁴ The expression of the path of motion is also sustained by the German morphosyntactic case-marking as it is the accusative which is being used for the expression of a motion along a path towards a goal (for more details see De Knop 2010).

(28'') 'Colin Firth a remporté l'Oscar pour son film « The King's speech » en bégayant.'

In this example it is impossible to translate the path of motion into French. So, the great difference between German and French is that German expresses motion solely with a satellite expressing the path of motion whereas French expresses the path of motion with a full verb. The German expression of manner (but not of motion) is in a way "alien" in the French translations.

2.7. Patterns with Modal Verb + Path Satellite

Let us close the description of the different realizations of the manner dimension in expressions of motion with a closer look at patterns with a modal verb and a path satellite. The main verb (= infinitive) expressing motion is missing (but in a deeper structure present):

(29) *Mein Bruder will in die Schule (gehen).* Lit. 'My brother wants (to go) to school.'

(30) *Er darf über die Straße (gehen).* Lit. 'He may (go) over the street.'

The main verb expressing the path of motion can be skipped because the path of motion is expressed by the prepositional group (*in die Schule/über die Straße*). Here we can refer to the 'economy-of-form factor' described by Filipovic and Vidokovic (2010: 284). With the modal verb it is the expression of manner which is prevailing. Such patterns are not possible in Romance languages because the path of motion cannot be expressed by a satellite like in German.

2.8. Summary

With the description of the expression of motion events in German it has become clear that the expression of manner pervades all levels of linguistic complexity, i.e., the level of simplex verbs, of complex local adverbs, of complex prepositional groups or of complex constructions. The expression of the manner of motion is often conflated with the expression of path. This is particularly obvious with complex local adverbs, with complex prepositional groups, or with particle verbs. The different possibilities are summarized in Table 2.

The strength of the German language is its great flexibility in the combination of path and manner expression in compact or synthetic groups, e.g., compound verbs, compound adverbs or prepositional groups. Translation difficulties of German expressions of motion into a Romance language very much result from the synthetic character of these expressions conflating path and manner in one (compound) expression. Romance languages favour more analytic expressions of these two dimensions, clearly separating path from manner, often even omitting the expression of manner. Let us now turn to the difficulties encountered by French-speaking learners of German.

Table 2. Different expressions of manner and path of motion

	Syntactic Structure	Path Expression	Manner Expression
(i) Motion verbs	Simplex V	(Satellite)	Different motion Vs
(ii) Location verbs	Simplex V	(Satellite)	Different location Vs
(iii) Complex local adverbs	Compound adverb	Particle for expression of vantage point (<i>hin-/her-</i>)	Preposition 2
(iv) Complex prepositional groups	Complex prepositional group (<i>bis</i> + Prepos. Phrase introduced by Prepos. 2)	Preposition <i>bis</i>	Preposition 2
(v) Constructions with complex particle verbs	Compound V (+ Satellite)	Particle (+ Satellite)	Non-motion V
(vi) Constructions with non-motion verbs	Simplex V + Satellite	Satellite	Non-motion V
(vii) Patterns with modals	Modal V + Satellite	Satellite	Modal V

3. DIFFICULTIES ENCOUNTERED BY FRENCH-SPEAKING LEARNERS OF GERMAN

Since Slobin's contrastive studies (1996 and 2000) of English and Spanish it is clear that learners belonging to a verb-framed language like Spanish encounter difficulties when learning a satellite-framed language. In the previous section we have described the differences in the expressions of manner (and path) between the satellite-framed language German and the verb-framed language French. This section will present and discuss the results of some tests done with French-speaking learners of German which confirm these difficulties.

3.1. Simplex Motion Verbs

As we saw in 2.1., German will use a variety of motion verbs depending on the manner of motion whereas French uses a very general verb, e.g., *aller* for all sorts of motion. This differentiated use in German is not optional but belongs to the correct way of expressing motion. This difference between the Germanic and the Romance language leads to difficulties which were confirmed by a test conducted with 34 French-speaking students of the B2/C1 proficiency level of the bachelor studies of Germanic languages. They were asked to translate 20 motion and location sentences from French into German. Here are some examples:

- (31) *Cet été ma tante ira aux Etats-Unis.* ‘This summer my aunt will go to the United States.’
 (32) *Pierre entre dans la cuisine.* ‘Pierre goes into the kitchen.’
 (33) *En été, nous allons à la mer du Nord.* ‘In the summer we go to the North Sea.’

The results confirmed our expectations: only 31% of the students used the correct motion verb in their German translation, which suggests that the great majority of French-speaking students (69%) underused the motion verbs as needed in German. In most wrong answers we found the very general verb *gehen* ‘to go’ which is a reproduction of the French lexicalization pattern with *aller*. Sometimes, a wrong motion verb was used, e.g., the verb *setzen* ‘to set’ for a bottle that is put into the fridge in a vertical or horizontal position.

3.2. Simplex Location Verbs

The same problems occurred with another translation test that concerned the use of German location verbs like *sitzen* ‘to sit’, *stehen* ‘to stand’ or *liegen* ‘to lie’ (see 2.2.). Fifteen French-speaking students (B2/C1 level) of the bachelor studies of Germanic languages were asked to translate 20 motion and location sentences from French into German, e.g.,

- (34) *Le bébé est dans sa chaise d'enfant (der Kinderstuhl).* ‘The baby is in its high-chair.’
 (35) *Où est le téléphone? Sur la table près du fauteuil.* ‘Where is the telephone? On the table near the settee.’
 (36) *L'enfant est dans son lit.* ‘The child is in its bed.’

Here again the translations by the French-speaking students were characterized by an underuse of the proper German location verb: only 38% of the students used the correct German verb. The uncorrect answers (62%) were characterized by a predominance of the very general verb *sein* ‘to be’. Consequently, the manner of motion is not expressed by French learners of German.

3.3. Constructions with Complex Particle Verbs

Examples of compound verbs consisting of a path particle and a non-motion simplex verb are very productive in the German press, e.g.,

- (37) *Am selben Abend wurde in Jette Joops 40. Geburtstag hineingefeiert.*
 (netzzeitung.de 18. Feb 2008 13:20)
 Lit. ‘On the same evening Jette Joop’s birthday was celebrated into.’

It seems that French speakers have many difficulties in understanding such examples, as shown by a translation test from German into French. Eighteen French-speaking students (B2/C1 level) from a Department of translation and interpretation studies at a Brussels high school were asked to translate 10 German sentences with such complex particle verbs. The manner dimension – which in German is expressed by the non-motion simplex verb with

which the satellite is compounded – was translated in 40.6% of the examples. This last figure has to be relativized as some of the translations into French proposed by the students were in principle correct but very unusual (2.8%), so that only 37.8% of the translations were considered to be acceptable. Still, this figure remains rather high compared with the claims in different studies (see e.g., Slobin 2000) that the manner of motion is scarcely translated or even completely omitted in translations by speakers of Romance languages. We can imagine that it is the focus on the main German verb – the main verb being the privileged lexicalization pattern for the expression of path in French – which allows us to explain why students translated the manner of motion at such a high rate. This assumption would also justify why the path of motion in the German examples was correctly translated in only 30.6% of the examples: as the path of motion is expressed by a satellite, i.e., a particle as the first constituent of the compound verb – a lexicalization pattern which is not present in French – there is a tendency not to express it at all in the translated sentences. Also the synthetic character of the German motion expression altogether (path + manner in one single compound) seems to be problematic for French speakers. Last but not least, the whole German construction in which the compound is being used is completely different from the French construction (see Section 2.5.); this can be a further cause for the impossibility to translate the German sentences at all (in 13.3% of the cases).

3.4. Constructions with Non-Motion Verb + Path Satellite

Similar observations have been made with a test which concerned German constructions with a non-motion (manner) verb and a separate particle, e.g., (28) *Colin Firth hat sich im neuen Film «The King's speech» zum Oscar gestottert* (Lit. 'Colin Firth stuttered himself in his new film «The King's speech» to the Oscar'). The same group of eighteen French-speaking students was asked to translate 10 sentences with a non-motion verb accompanied by a path satellite. The translation of the manner of motion succeeded in 37.2% of the sentences, but again some of them were awkward or unusual (5%), which means that only 32.2% of the translations were acceptable. The path of motion was correctly translated in 31.1% of the examples.

In 26.1% of the sentences the students were unable to propose a translation at all. This is probably due to the difference between the German and the French constructions. It is not enough to know the meaning of the non-motion verb and of the path satellite to understand what is exactly meant. Here again the problems can be explained by the use of a satellite in German to express the path but which is combined with a non-motion verb expressing the manner of motion, a lexicalization pattern not available in French.

The manner dimension is more rarely expressed in French but if it is expressed at all then with different means:

(i) with a gerund, e.g.

(26) *Letzte Nacht klingelte ein Unbekannter die Bundeskanzlerin Merkel aus dem Schlaf.*

Lit. 'Last night an unknown (person) rang the chancellor Merkel out of the sleep.'

→ 'La nuit dernière, un inconnu a réveillé la chancelière Angela Merkel en sonnant'.

(ii) with a nominal group, e.g.

- ‘La nuit dernière, un inconnu a réveillé la chancelière Merkel à coups de sonnette’.
 (iii) with different main verbs:
 → La nuit dernière, un inconnu sonna chez la chancelière Merkel et la réveilla.

3.5. Summary

The following Table 3 brings a summary of the test results for the translation of simplex motion or location verbs. There is an underuse of different motion verbs by French-speaking learners of German and consequently a lack of expression of the manner of motion.

Table 3. Results of the translation test (simplex motion and location verbs)

	Correct translation: several distinctive motion verbs	Uncorrect translation: one single general verb
Simplex motion verbs	31%	69%
Simplex location verbs	32%	68%

The following Table 4 summarizes the results of the translation tests of complex particle verbs and constructions with a path satellite + a non-motion verb.

Table 4. Results of the translation tests (complex particle verbs and path satellite + non-motion verb)

	Translation of manner	Unusual translation of manner	Translation of path	Impossibility to translate
Complex particle verb	37.8%	2.8%	30.6%	13.3%
path satellite + non-motion verb	37.2%	5%	31.1%	26.1%

Both tables clearly show that the expression of the path and the manner of motion is not so explicit in the French translation of the German constructions.

CONCLUSION AND PERSPECTIVES

In his description of motion events Talmy claims (2000: 152) that the path of motion is the most basic information in a motion event, while manner is a subsidiary one. After we have shown that German is very much characterized by a salience of the manner expression at different linguistic levels, this claim can be revisited and differentiated; in German it seems that the two dimensions of the path and the manner of motion play an almost equally important role. This is sustained by the German categories of examples in which the path and manner of motion are concomitantly realized in one and the same word, i.e., compound particle verbs, or one and the same construction, i.e., with a path satellite and a non-motion

manner verb. Such constructions are problematic for French speakers as the motion event is realized by a particle satellite in German which expresses the path of motion. French on the contrary generally expresses the path with a full verb. Manner is additionally expressed in German at the level of the non-motion verb.

The translation tests with our French-speaking students learning German brought to the fore that the typological differences between French and German are not unproblematic in the learning process: (i) the manner dimension is often skipped, e.g., with motion and location verbs, and (ii) constructions with particle verbs consisting of a path particle and a manner verb or constructions with a non-motion verb and a path satellite are difficult to understand and to translate.

The question now arises of how to deal with the differences between French and German in foreign language teaching. First, it will be necessary to do some awareness-raising exercises which show the different conceptualizations in Germanic languages and the salience of the manner dimension in German. In a second step it will be necessary to illustrate in which patterns manner salience is realized in German. And finally a methodology for the teaching of the more difficult constructions will have to be developed. To put it with Lantolf (1999: 29-30) the real issue is “to what extent is it possible for people to become cognitively like members of other cultures; that is, can adults learn to construct and see the world through culturally different eyes?” This will require some more research and hence belongs to future perspectives.

Chapter 78

METAPHORICAL MOTION IN LINGUISTIC CONTEXT: PROCESSING IN ENGLISH AND SPANISH

Jill Hohenstein

King's College London, London, UK

ABSTRACT

For both literal and metaphorical motion, languages like English tend to express path in the satellite following the main verb of the sentence, freeing the verb to convey manner of motion information. In contrast, languages like Spanish tend to express path of motion in the main verb and less often directly convey manner of motion. Interestingly, theories about metaphor processing differ in the emphasis they give to cross-linguistic differences. In two studies, the current investigation examined 60 (30 English-speaking, 30 Spanish-speaking) adult participants' judgments about and reaction times for literal and metaphorical motion in familiar phrases (Experiment 1) as well as novel motion event metaphors (Experiment 2). Results suggest that English speakers both more frequently identified familiar metaphorical sentences when they included a manner verb and were faster at making these judgments than were Spanish speakers. With novel metaphors, English speakers picked the literal match at a proportionally greater rate than did Spanish speakers and did so more slowly than did Spanish speakers when sentences contained a path verb. These results indicate that English and Spanish speakers approach the task of interpreting metaphors in different ways depending on the type of verb that is used in the sentence.

Keywords: motion event typology, conceptual metaphor, graded salience, career of metaphor, linguistic variation

1. INTRODUCTION

Conceptual Metaphor Theory (CMT; Lakoff and Johnson, 1980) highlights how metaphors occur regularly in everyday conversation, often in such a way that people are not conscious of them. Research on Conceptual Metaphor Theory generally uses common

metaphorical concepts, in which the target is related to a source or base, to categorize metaphorical expressions (e.g., MORE IS UP, LOVE IS A JOURNEY). This phenomenon of metaphorical language is fundamentally connected to the study of the relation between thought and language. If, as has been suggested by Conceptual Metaphor Theory, metaphor is not just a way of speaking but also the grounds for thinking, then differences across languages in the way metaphor manifests should be associated with differences in thought as well. The current study sought to compare the way speakers of two languages (English and Spanish) process both novel and familiar metaphorical motion sentences.

The idea that metaphor is a universal foundation for much of the way individuals talk and think has inspired research on how influential metaphor and other figurative speech can be on processing of language. Multiple studies have shown that the processing of utterances can be just as easily done when the expressions are metaphorical as when they are literally intended (Nayak and Gibbs, 1990; Gibbs and O'Brien, 1990; Allbritton, McKoon and Gerrig, 1995; Gibbs, Bogdanovich, Sykes and Barr, 1997). On the other hand, recent brain studies suggest that "accessing the meaning of words in metaphoric expressions is performed using the regular comprehension mechanisms but is more difficult" than is accessing the literal meanings of words (Arzouan, Goldstein and Faust, 2007, p. 70). So, while these results might imply that the processing of metaphor happens through the same channels that literal language processing uses, there still may be some disadvantage for metaphor. Processing of metaphor through the same mechanisms as literal language is consistent with the idea that metaphor is used to structure how people think in a foundational sense. However, some have begun to question the idea that all metaphorical language is necessarily connected to metaphorical thought, especially when the metaphors have been taken on in conventional language (e.g., Keysar, Shen, Glucksberg and Horton, 2000).

Lexical Concepts and Cognitive Models (LCCM, Evans, 2010), suggests that processing of both literal and figurative language relies on, in addition to a set of universal conceptual metaphors, individuals' integration of background knowledge with information that has been taken in through language in general sense-making. LCCM proposes that linguistic interpretation is mediated by both salience and complexity. In examples Evans provides, in which various items are introduced as 'intoxicants', things that are normally associated with intoxication, like whiskey, are more easily integrated into sentences such as "He knows whiskey is an intoxicant" than are other subjects, such as cough syrup and power, which are integrated decreasingly easily due to their increasing complexity (2010, p. 608). The complexity in this example comes from both normal association (or lack thereof) and relation of apparently incongruent ideas. In addition, Evans's ideas on salience stem from Giora's findings that novel metaphors are processed more slowly than are familiar ones due to the relevance familiar metaphors have for everyday thought (1999). Salience may be particularly relevant to understanding linguistic variation in the use and comprehension of metaphor and so is further detailed here.

Two theories have addressed the way in which metaphors may become salient in everyday language: the Career of Metaphor proposes a developmental process by which a novel metaphor can become conventionalized with repeated exposure; and the Graded Salience Hypothesis suggests that people will react more quickly to the meanings of words and phrases that are most conventional for their cultural situation, regardless of whether they are metaphorical or literal. Each of these theories is outlined below.

The Career of Metaphor theory (Bowdle and Gentner, 2005; Gentner and Wolff, 1997) proposes that new metaphors might be understood through a relatively laborious process the first time they are encountered and only later, with greater practice/rehearsal, would they be recognized in a rapid, relatively effortless manner. This model of processing suggests that new or novel metaphors would require effortful alignment of the target and base in order to be understood. However, once these metaphors have become habituated into the thinking of a person, they would be understood through a process of categorization, which would require less time and effort than alignment. A more conventional metaphor would only require the recognition of the mapping, not the search for relevant properties. As a result, according to this idea, novel metaphors would require processing through comparison of the base and target in order to map the necessary elements of similarity.

Consistent with the Career of Metaphor is the Graded Salience Hypothesis, which takes into consideration how salient different potential meanings of the same words might be to different speakers (Giora, 1999, 2002; Giora and Fein, 1999). According to this theoretical perspective, both a literal and a metaphorical meaning should be activated upon encountering a metaphorical expression. However, the most salient meaning will be processed first in this case. Thus, it is difficult to disregard a highly conventionalized metaphorical meaning even when the context supports a literal meaning. For instance, Giora (1999) has suggested that in highly familiar metaphors (perhaps idioms), such as ‘read my lips’ in English, individuals would process the metaphorical meaning ‘pay attention to what is said’ while also processing the request to use lipreading as a device to communicate in circumstances that called for absolute silence (p. 491). And for certain people, particular phrases may be more conventionalized than they would be for other people. Giora (2002) suggests that, for example, reference to the *West Bank* as meaning “occupied territories” is more salient to people living in Israel compared with people from elsewhere because of its immediate relevance to the political situation in Israel. In a study examining relatively familiar versus relatively novel metaphors, Giora and Fein (1999) found that familiar metaphors activated a metaphorical and a literal meaning in both literal and metaphorically biasing contexts. In contrast, less familiar metaphors only activated the metaphorical meaning in a metaphorically biasing context, not a literally biasing context. Both the Career of Metaphor and the Graded Salience Hypothesis might be useful in considering the ways that metaphors differ (or are the same) across cultures because of the way they consider habituation or salience for prediction of processing effort. Differences in salience or habituation may be related to linguistic context and will be investigated here in terms of motion event metaphors in English and Spanish.

1.1. Linguistic Variation in Metaphor

Kövecses (2005) has examined the use of metaphors in many distinct languages and found that there are some potentially universal conceptual metaphors (e.g., THE ANGRY PERSON IS A PRESSURIZED CONTAINER). In contrast, languages often construe the same metaphorical sources (e.g., anger) using targets that vary in how they relate to the source concept. According to Kövecses, the ways targets might differ include the amount of specificity in language that is expected, the degree of transparency of the metaphor and the degree of conventionalization, among others. He uses examples from Spanish and English in

metaphors about anger to show that whilst general metaphors can be acceptable in both languages (see example 1), in many cases more specific language used in metaphorical ways is accepted only in English (example 2).

1. a. "She went crazy."
b. "Ella se volvió loca." (She turned/became crazy).
2. a. "The news threw him into a terrible state of anxiety."
b. * "Las noticias lo lanzó al interior de un terrible estado de ansiedad."
(The news threw him into the middle of a terrible state of anxiety). (Kövecses, 2005, p. 154).

So, whereas the source of the metaphor is the same in all cases, only English can use the specific target language of 2a in realizing the metaphor. This restriction is probably related to the typology of motion event description in Spanish as detailed in the next section.

1.2. Motion Event Typology

Talmy (1985, 1991, 2000) noted that some languages, like English and German, generally express the path or direction of motion in a post verbal phrase and may use the main verb of the sentence to express other facets of motion, like manner (e.g., waddles *across the street*). These languages are known as satellite-framed, or S-languages, because they typically convey path of motion in a satellite of the main verb. On the other hand, many languages (e.g., Romance languages, Hebrew, Turkish, Greek, Korean) tend to place the path of motion in the main verb of the sentence and when they include description of the manner, often do so with a postverbal construction like a gerund or prepositional phrase (e.g., *cruce la calle, anadeando/crosses the street, waddling*). Such languages can be thought of as verb-framed (V-languages).

In support of this typological distinction, Naigles, Eisenberg, Kako, Highter, and McGraw (1998) found that, in describing videos of motion events, monolingual Spanish speakers used manner verbs in only 33% of their utterances, whereas monolingual English speakers used them in 91% of their utterances. This same basic pattern in S- and V-languages has been demonstrated in picture book narration (Berman and Slobin, 1994), bilingual speakers' interlanguage (Hohenstein, Eisenberg & Naigles, 2006), speakers' willingness to assign novel verbs to actions (Cifuentes-Férez and Gentner, 2006; Naigles and Terrazas, 1998), "Thinking for Speaking" (Gennari, Sloman, Malt and Fitch, 2002, Papafragou and Selimis, 2010), as well as non-linguistic thought (Hohenstein, 2005; Papafragou, Hulbert and Trueswell, 2008; though see Cardini, 2010 for conflicting results). As is apparent in this sample of literature in typology and cognition regarding motion events, the topic is widely researched with respect to literal language. Research is also beginning to appear in metaphorical motion event language.

1.3. Metaphorical Motion

Metaphorical motion involves the use of motion event language in the expression of ideas not involving motion as in Examples 1 and 2 above or in such sentences as “*Sally climbed to power by trampling on her co-workers*”, where it would be a highly unusual form of employment that could result in the literal intention of “climbing” and “trampling”. Work with metaphorical motion has begun to show that literal motion event language patterns are also present in metaphorical motion event language in both in adults (Özçalışkan, 2003; Wilson, 2006) and children (Özçalışkan, 2005). In her work with English- and Turkish-language newspapers, novels and spoken language, Özçalışkan (2003, 2005) found that across all sources in her study, English speakers used a higher percentage of manner verbs than did Turkish speakers when conveying metaphorical motion. At the same time, there were few differences between language groups in either primary or complex metaphorical mappings. That is, the types of concepts that appeared in metaphorical language did not differ across languages; only the way they appeared was language specific. Wilson (2006) obtained similar results with English and Spanish speaking monolinguals as well as bilinguals. Though speakers of both languages used similar metaphorical mappings, they did so in ways that were typical of their language pattern for literal motion.

1.4. Current Research

Given the previous work on the processing of metaphor and the research on typology and cognition related to motion event language in V- and S-languages, the current study set out to examine how metaphorical motion is processed by speakers of English and Spanish. The assumption of CMT is that when metaphors in English and Spanish express the same meaning, the underlying conceptual metaphors ought to be the same, regardless of surface structure. But how would these metaphors be processed in the different languages? It may be the case that linguistic variation affects the Career of Metaphor (Bowdle and Gentner, 2005) or that language typology affects the salience of particular phrases as in the Graded Salience Hypothesis (Giora 1999, 2002). As such, examining reactions to metaphors by people who speak different languages may reveal differences in how speakers process metaphorical language.

Two tests were designed to measure how speakers react to metaphorical motion in familiar phrases (Experiment 1) and novel phrases (Experiment 2). If the prominence of manner verbs in English motion event language heightens their salience in metaphorical motion, we would predict that English speakers would be more likely to recognize phrases as metaphors when they contain manner verbs than when they contain path verbs and that further, reaction times would be facilitated for metaphorical motion with manner verbs. Similarly, the identification of metaphors that contain path verbs should be salient and happen more regularly for Spanish speakers than identification of manner verb metaphors if the appearance of path verbs in the language more regularly is an influential force.

2. EXPERIMENT 1

The first experiment was designed to determine whether differences in typical language for metaphorical motion would influence speakers' recognition of familiar metaphors in normal isolated sentences. As such, participants read sentences depicting motion, either real or metaphorical, with either manner verbs or path verbs, and were asked to judge whether they represented literal or non-literal motion.

2.1. Method

2.1.1. Participants

Monolingual speakers of English and Spanish dominant individuals (but not monolingual in Spanish) were recruited to participate in this study. Each group consisted of 30 adults (English: 15 men and 15 women; Spanish: 16 men and 14 women) between the age of 25 and 40 (English $M = 33.14$, $SD = 4.09$, Range = 26-40; Spanish $M = 32.60$, $SD = 4.45$, Range = 26-39). There were no differences in age between groups.

Recruitment was carried out for both groups through a 'snowball' technique. This method utilizes acquaintances of the researcher, who then put the researcher in touch with acquaintances of theirs.

English speakers reported they did not know any other language beyond a 'travel' ability. Spanish speakers reported knowing English to varying degrees, some fluent, some conversational. None had begun learning English before the age of 7 in classes at school. Because this study was conducted in England, a nation in which anyone residing there would be expected to know some English, it was not possible to work with monolingual Spanish speakers. In addition, Spanish speakers were mostly born in Spain (25) but several came from Latin America (Mexico, Venezuela, Argentina, Dominican Republic). These points will be returned to in the discussion of results. However, note that being bilingual would – if anything – minimize the possibility of finding differences between groups.

Instruments. Stimulus materials consisted of sentences containing motion event verbs in English and Spanish. Sentences in each language had the same meaning. As much as possible, sentences were controlled for length such that a sentence in English had the same number of morphemes as the corresponding sentence in Spanish. On average, Literal sentences were 8.4 morphemes long in English and 8.2 morphemes long in Spanish, whereas Figurative sentences were 8 morphemes long in English and 7.5 morphemes long in Spanish.

There were 10 sentences depicting literal motion and 10 depicting metaphorical motion in each language. Within literal and metaphorical motion sentences, 5 contained a manner verb and 5 contained a path verb. The full list of sentences used in the experiment can be seen in Appendix A. However, to provide an example, Sentences 3a and 3b depict metaphorical motion with a path verb in English and Spanish.

3. a. "They have passed through this before."
b. "Ya han pasado por esto antes."
4. a. The little girl tripped over the jump rope.
b. La niña se tropezó con la cuerda de saltar.

Sentences 4a and 4b show literal motion with a manner verb in English and Spanish. The test sentences were generated in English first and then translated by a native speaker of Spanish¹. Those sentences that matched in verb type used in both languages were selected for use in the experiment.

Metaphorical sentences were rated as to their level of conventionality by 35 native English-speaking undergraduates who did not take part in the rest of the study. These undergraduates rated each sentence on a scale of 1 to 5, where 1 represented ‘highly unconventional’ and 5 represented ‘highly conventional’. Results show that these sentences were rated significantly more conventional ($Mean = 4.18$, $SD = 0.56$, $Mode = 5$), than would have been expected by chance (2.5), $t(34) = 19.04$, $p < .001$. Thus, the sentences are thought to be relatively conventional metaphors.

2.1.2. Procedures

The experiment was conducted on a MacBook G5 with a 13-inch screen using Superlab 4.0.7b. Stimulus materials were presented one at a time in an order randomized by Superlab.

Participants were tested individually in a quiet area while seated comfortably in a chair either with the laptop on a table in front of them or on their laps. Following reading and signing the consent form, participants read instructions on the computer screen. These instructions pointed out that some motion language refers to real motion, whereas other language refers to motion that is not real. It was then indicated that they should press the letter ‘F’ when they read a sentence they thought represented literal motion and the letter ‘J’ when the sentence represented non-literal motion. These instructions also informed the participant that reaction time was a factor and that they should make their choices as quickly as possible.

2.2. Results and Discussion

In order to address the ways that speakers of English and Spanish responded to real and metaphorical motion, data were treated in two ways: First, responses as to whether sentences were metaphorical or literal were noted and compared across language groups and verb type. Next, reaction times were compared in the same categories.

It should be noted that some Spanish sentences (and their English equivalents) were excluded from analysis after it was discovered that they were conventional only in Mexican Spanish. Three native speakers of Spanish from Spain selected sentences that constituted novel, rather than familiar, metaphors in Spain. As a result, four metaphorical sentences were removed from the dataset (two manner verbs, two path verbs), leaving six metaphorical sentences and ten literal motion sentences. See Appendix A for details of which sentences were used.

To summarize the data obtained in judgments of whether sentences were or were not metaphorical, Table 1 shows the number of responses to the metaphorical and literal sentences with manner or path verbs separately by language group.

¹ The native Spanish speaker was a speaker of Mexican Spanish. This became an issue when Spanish speakers from different regions participated in the study. Some sentences were eliminated. This is discussed in the Results section of each Experiment.

Table 1. Number of English speakers' and Spanish speakers' literal and metaphorical responses to literal and metaphorical sentences by type of motion verb

	Responses			
	English		Spanish	
Stimuli	Literal	Metaphorical	Literal	Metaphorical
Literal				
Manner	135	15	137	12
Path	130	20	126	24
Metaphorical				
Manner	9	81	23	65
Path	34	55	42	48
Total	308	171	328	149

Looking across manner and path, English and Spanish speakers differed in their choices of which sentences were metaphorical, $\chi^2(1) = 3.86$, $p = 0.05$, with English speakers picking metaphorical relatively more frequently than Spanish speakers when the sentence was metaphorical. In contrast, collapsing across the literal and metaphorical sentences, English and Spanish speakers did not differ in their choices depending upon whether the verb was manner or path, $\chi^2(1) = 0.26$, n.s. When examining the manner verb sentences only, English speakers had relatively more metaphorical responses when the sentence was metaphorical compared with Spanish speakers, $\chi^2(1) = 5.31$, $p = 0.02$. No differences between language groups were found in path verb sentences. That is, English speakers seem to respond more readily to manner verb sentences, as would be predicted by a developmental or usage based theory; Spanish speakers did not.

In order to analyze the reaction time data, responses that did not correspond to the expected one (literal or metaphorical) were removed. In this way, only 'correct' judgments of literal and metaphorical manner and path were included in the analysis. Then response times that were less than 200ms were removed as they are deemed to not be valid judgments (most of these had already been removed when unexpected answers were removed). Next the inverse was taken for reaction times as recommended by previous research (Greenwald, Nosek and Banaji, 2003; Ratcliff, 1993). The inverse value represents the speed of response as opposed to the latency, which is represented by the raw data. For clarity, means and standard deviations here are provided in latencies, though all analyses have been reported on inverted times².

Overall latency times by language group were 3496ms for English and 4281ms for Spanish and these were not significantly different. A further examination of the responses was conducted using a two-way repeated measures ANOVA, where Verb Type (manner, path) and Figurativity (literal, metaphorical) served as within-subjects variables, with Language (Spanish, English) as a between-subjects variable. Results suggest main effects of Verb Type, $F(1, 51) = 12.68$, $p = .001$, $\eta^2 = .20$, Figurativity, $F(1, 51) = 23.48$, $p < .001$, $\eta^2 = .32$, and two-way interactions between Verb Type and Language, $F(1, 51) = 5.80$, $p = .02$, $\eta^2 = .10$, and Verb Type and Figurativity, $F(1, 51) = 23.43$, $p < .001$, $\eta^2 = .32$. As can be seen in

² Analyses were also carried out on latencies, removing responses that were at least 2 Standard Deviations above the mean. While results were similar (albeit not as robust), inverted values were used in this report because the distribution of data was deemed closer to normal.

Figure 1, participants were faster overall at responding to manner verb sentences than they were to path verb sentences.

However, using paired comparisons, this was more evident of the English speakers, $t(29) = 3.75$, $p = .001$, $\eta^2 = .11$, than it was of Spanish speakers, $t(29) = 1.58$, n.s., which is consistent with the idea that English speakers would be more accustomed to hearing manner verb sentences than would Spanish speakers. In addition, participants were also faster at responding to literal sentences than to metaphorical sentences. In fact, participants responded more rapidly to literal manner verb sentences than they did to literal path verb sentences or metaphorical sentences of either verb type, all $t_s > 4.68$, $p_s < .001$, all $\eta^2 \geq .13$. The variance in the different categories appears great in the real response time values, particularly in the case of Spanish speakers' metaphorical path verb responses. However, the inversions show much less variance.

Figure 1. Means (error bars represent Standard Error) of Spanish and English

Hence, in the manner categories Spanish speakers took longer speakers' latencies in ms across literal and metaphorical uses of manner and path by verb type than did English speakers to respond correctly as to the literal or metaphorical character of the sentence. This was not true of the path verb sentences. The results of this study suggest that in judging sentences, English speakers identified metaphors more frequently than did Spanish speakers when the sentences contained a manner or a path verb. They were also quicker to respond to sentences with manner verbs (both literal and metaphorical) than were Spanish speakers. However, because the metaphors were fairly conventional, these were all sentences that participants should have been able to recognize. The next study examines how speakers of each language react to novel metaphorical uses of manner and path motion verbs.

3. EXPERIMENT 2

The second experiment was designed to determine how likely English speakers and Spanish speakers were to accept a new metaphorical motion expression. The items were divided between novel metaphors and familiar metaphors, each using either a manner or a path verb.

3.1. Method

3.1.1. Participants

The same participants took part in Experiment 2 following their involvement in Experiment 1.

3.1.2. Instruments

An additional 20 sentences were devised for this experiment. Ten of these sentences contained manner verbs and ten used path verbs. Half of each of these groups of sentences represented familiar metaphors and half were novel metaphors. Again, attempts were made to use sentences in English and Spanish that contained the same number of morphemes. This time Novel metaphors averaged 9.9 morphemes long in English and 10.1 morphemes long in Spanish, with Familiar metaphors averaging 8.86 morphemes in English and 9.71 in Spanish. Sentences were judged as to their conventionality by the same undergraduate students who rated the sentences in Experiment 1. Again, participants rated each sentence on a scale of 1 to 5, where 1 represented 'highly unconventional' and 5 represented 'highly conventional'. Novel sentences were rated significantly less conventional ($Mean = 2.39$, $SD = 0.44$, $Mode = 2$) than were familiar sentences ($Mean = 4.38$, $SD = 0.36$, $Mode = 5$), $t(34) = 29.63$, $p < .000$. Thus, the novel sentences should have seemed less recognizable as metaphors than did the familiar sentences.

When sentences appeared on the screen, they were accompanied by two photographs. Half of these photographs were literal depictions of the sentence, whereas the other half portrayed metaphorical meanings of the sentence. Literal and metaphorical depictions were presented half of the time on the left side of the screen and on the right side of the screen for the remainder. Participants were instructed to press the 'F' key when they thought the sentence matched the picture on the left and the 'J' key when they thought it matched the picture on the right. The experimental procedure was otherwise the same as that used in Experiment 1.

The full list of sentences can be seen in Appendix B. However, for purposes of illustrating the types of sentences used, sentences 5a and 5b below show novel manner verb use in English and Spanish.

5. a. "He danced through the menu."
b. "Bailó por el menú."
6. a. "We were circling that movie for hours."
b. "Rodeábamos varias horas alrededor de la película."

Sentences 6a and 6b show novel path verb use in English and Spanish. As in Experiment 1, sentences were generated first in English and then translated into Spanish by a native Spanish speaker. Sentences that matched in verb type in English and Spanish were selected for use in Experiment 2.

3.2. Results and Discussion

As with Experiment 1, it was necessary to eliminate some of the Spanish language sentences (and their English equivalents) due to the use of conventional Mexican phrasing. This was carried out for the familiar metaphorical statements only as the new metaphors did not exist in either language. Consequently, three of the manner verb sentences were removed from analysis. All of the remaining sentences were analyzed in two ways: First, choices of the metaphorical and the literal photos were examined in a nonparametric fashion by type of verb and novel/familiar metaphors. Next reaction times were analyzed by condition.

As is apparent in Table 2, both Spanish and English speakers more often gave a metaphorical than literal response. Indeed, this did not differ overall by language group, $\chi^2(1) = 3.07$, n.s. However, in the Novel Path condition English speakers picked the literal match at a proportionally greater rate than did Spanish speakers, $\chi^2(1) = 4.63$, $p = 0.03$. Within the other conditions there were no differences between language groups, all $\chi^2 < 2.4$.

Table 2. Frequencies of literal and metaphorical representations picked by English and Spanish speakers, separated by Verb Type and Novelty

	Responses			
	English		Spanish	
Stimuli	Literal	Metaphorical	Literal	Metaphorical
Familiar				
Manner	22	38	14	45
Path	22	128	22	127
Novel				
Manner	30	120	31	117
Path	57	93	39	109
Total	131	379	106	398

In terms of reaction times, the latencies, collapsing across sentence type for each language group were 6367ms (English) and 6357ms (Spanish), which were not significantly different. As in Experiment 1, a two-way ANOVA with Verb Type (manner, path) and Novelty (novel, familiar) as the within-subjects variables and Language (Spanish, English) as a between-subjects variable was run on the dependent variable Speed (inverse latency). Figure 2 shows the latency responses that are reflected in the current analyses of speed of reaction. There was a main effect of Verb Type, $F(1, 58) = 11.05$, $p = .002$, $\eta^2 = .16$, where participants responded faster to manner verb sentences than they did to path verb sentences. This was true across both types of metaphorical sentence (novel and familiar). In addition there was a main effect of Novelty, $F(1, 58) = 39.58$, $p < .001$, $\eta^2 = .41$, in which participants were faster to respond to familiar metaphors than they were to respond to novel ones. Finally,

a three-way interaction between Verb Type, Novelty and Language, $F(1, 58) = 3.42$, $p = .06$, $\eta^2 = .08$, was close to significant. Given the relevance to the hypotheses, this interaction was explored further, even though significance is deemed only marginal. The examination of reaction times in novel and familiar metaphors using paired comparisons led to only one significant distinction between speakers of English and Spanish. While English and Spanish speakers generally performed similarly to each other in the different conditions, English speakers were significantly slower than were Spanish speakers at deciding in the Novel Path condition, $t(58) = 2.23$, $p = 0.03$, $\eta^2 = .07$ (other differences were inconsequential, $t_s < 1.3$). As such, English speakers were both slower and picked the literal photograph more often than did Spanish speakers in the Novel Path condition suggesting that Spanish speakers were more likely than were English speakers to accept new metaphors when they contained a path verb.

Figure 2. Means (error bars represent Standard Error) of English and Spanish speakers' latencies in ms to novel and familiar metaphors by verb type.

4. DISCUSSION

Spanish speakers and English speakers behaved differently from each other in the two different experiments. English speakers were faster in Experiment 1 at identifying sentences that contained manner verbs in both the literal and metaphorical motion conditions. Additionally, English speakers identified metaphorical sentences correctly more often than did Spanish speakers, especially when the metaphorical sentence contained a manner verb. In

Experiment 2 however, Spanish speakers were faster than were English speakers at responding to novel metaphors when there was a path verb in the sentence. Likewise, Spanish speakers were more likely to accept a novel metaphor that contained a path verb than were English speakers.

Results from these two experiments seem to indicate that processing of metaphor is facilitated in English speakers by the use of a manner verb and in Spanish speakers by use of a path verb. However, the results are not entirely clear cut. In distinguishing between familiar literal and metaphorical sentences, only manner verbs seemed to act as a facilitating mechanism. In other words, Spanish speakers were not faster at recognizing metaphors when they contained a path verb in that experiment. In addition, in the second experiment, only path verbs but not manner verbs acted as a facilitating agent and only for novel metaphors. So when English-speaking participants were asked to judge which photograph most suited the sentence on the screen, manner verbs did not significantly increase the likelihood of a metaphorical choice or the time of response. Why would the two experiments lead to results that differed in this way? It may be that the exclusion of three sentences in the novel manner condition in Experiment 2 decreased the chances of demonstrating differences between language groups. Alternatively, the presence of literal sentences in Experiment 1 may have provided a cue for English speakers (more than for Spanish speakers) to pay attention to the typology. In contrast, Experiment 2 contained only metaphorical sentences and Spanish speakers may have somehow latched on to this in a way that made path verbs a facilitative element. It would be useful to test both novel and familiar metaphors in other contexts to investigate more fully the nature of cross-linguistic differences. Finally, the difference in method may have made a difference to the way participants responded. Pairing photographs with sentences may have been harder than identifying metaphors, especially for certain types of sentences (indeed, the response times are somewhat greater in Experiment 2 than in Experiment 1). This method seems to be novel and should be further explored to see how it might be used in future studies.

4.1. Limitations and Future Directions

As noted previously, the Spanish speakers who participated in this study were not monolingual speakers of Spanish. And in this era it is difficult to find middle-class Spanish speakers anywhere who do not also speak some English. Though it is true that this limitation would seem to diminish the likelihood of finding differences between the language groups, differences were found in the two experiments reported here.

Future work should address this concern by conducting data collection with Spanish speakers in a country where Spanish is spoken, preferably in a monolingual environment. Such a study could also eliminate the variation in dialects as occurred here.

In addition, some of the stimulus materials could not be used because the sentences were conventional only in Mexican Spanish, whereas the majority of Spanish speakers in this study came from Spain. Though many metaphorical sentences could still be used in this study, the sentences that were excluded mostly contained manner verbs (5/7). Nevertheless, not all the sentences had to be excluded and differences were still found in metaphorical manner sentences in Experiment 1.

4.2. Theoretical Implications

The differences found between the two language groups were predictable, albeit modest, based on the typology of Spanish and English in both literal and metaphorical language. As such, it would seem that the typical motion event language patterns would provide a source of salience or habituation for the recognition of metaphors.

Spanish speakers were quicker to respond to and more willing to accept novel metaphors containing a path verb than they were for manner verb metaphors and faster compared to English speakers. They were possibly more prepared to encounter and deal with metaphors in path verb format than manner verb format because of a habituation to this type of motion event language. The same may have occurred for English speakers in distinguishing literal from metaphorical sentences. For these speakers, the appearance of motion events (literal or metaphorical) in language typical patterns seemed salient.

These findings are not inconsistent with the idea that speakers of different languages operate using universal conceptual metaphors (Lakoff and Johnson, 1980). However, they are particularly supportive of the idea that metaphors are instantiated in different ways according to conventionalization (Kövecses, 2005).

Moreover, these results suggest that there is more to the identification of metaphor than merely reliance on an underlying conceptual metaphor. As such, the Lexical Concepts and Cognitive Models theory (Evans, 2010) that incorporates elements of Conceptual Metaphor Theory (Lakoff and Johnson, 1980) with the processing of both literal and metaphorical language through paying attention to context, including factors like salience and complexity, may go further in explaining the nature of metaphor comprehension.

In particular, both the Graded Salience Hypothesis (Giora, 1999, 2002) and the Career of Metaphor Hypothesis (Bowdle and Gentner, 2005) are supported to some extent here because it would seem that language typology is linked to some conventionalization and/or salience of the way events, even metaphorical ones, are expressed in particular languages.

In other words, while there may be some validity to the idea that conceptual metaphor is an underlying (in some cases universal) mechanism involved in processing metaphorical language, it seems that LCCM, through its context-based model of processing both literal and figurative language, may provide a more accurate perspective on how people make sense of linguistic input. So, though the conceptual metaphors may be the same across languages, the conventionality of typologically consistent language may create a sense of salience that helps speakers to process both metaphorical and literal sentences.

CONCLUSION

As with studies on typology and cognition to do with literal motion event language, there appear to be some differences between speakers of two different language types (S- and V-languages) in terms of the processing of metaphorical motion event language. Just as speakers of English and Spanish are likely to choose meanings of novel verbs in ways that correspond to their language typology (Naigles and Terrazas, 1998) and may be influenced in their “Thinking for Speaking” (Sloman et al., 2002) or even nonlinguistic cognition (Hohenstein, 2005; Papafragou et al., 2008), participants in this study differed in how they responded to

metaphorical motion event language in ways that could be predicted by the language typology. Like literal motion event typology, manner verbs appear more frequently in English speakers' metaphorical motion language and path verbs appear more frequently in Spanish speakers' metaphors (Wilson, 2006).

This study provides evidence that these typological patterns make a difference in the processing of metaphorical motion language.

Overall, as Kövecses (2005) has suggested, language variation does seem to play a part in both the expression and comprehension of metaphorical language, at least in the case of metaphorical motion.

APPENDIX A

Stimulus Sentences for Literal/Metaphorical (Familiar) Responses Used in Experiment 1

Literal pairs

Manner Verbs

And then I ran for an hour.

Y luego corrí una hora.

The little girl tripped over the jump rope.

La niña se tropezó con la cuerda de saltar.

The children were jumping on the bed.

Los niños saltaban en la cama.

People like to walk in the park.

A la gente le gusta andar en el parque.

I climbed the tree.

Me trepé al árbol.

Path Verbs

I went out through the main door.

Salí por la puerta principal.

The boy always crosses the street in the same place.

El niño siempre cruce la calle del mismo sitio.

Sometimes he goes down the back stairs.

A veces baja las escaleras al fondo.

She was going in the building behind the group of tourists.

Entraba el edificio siguiendo el grupo de turistas.

The truck was quickly approaching him.

Le acercaba rápidamente el camión.

Figurative pairs

Manner Verbs

We carried out the work that was required.

Llevamos a cabo el trabajo requerido.

*I think I will skip class tomorrow.

*Creo que me volaré la clase mañana.

We were thinking we could smooth over our differences.

Pensábamos que podríamos limar nuestras diferencias.

*I stumbled upon some news the other day.

*Me topé con unas noticias el otro día.

He threw her a nasty look.

Le echó una mirada terrible.

Path Verbs

They have passed through this before.

Ya han pasado por esto antes.

*I'm going with the flow.

*Voy con el corriente.

The price of stocks is rising.

Las acciones están subiendo de precio.

*I felt the anger was passing.

*Sentí que se me pasó el coraje.

The plague was spread by rats.

Las ratas propagaron la plaga.

* These sentences were eliminated from analyses because of the use of Mexican dialect in the metaphorical sentences.

APPENDIX B

Sentences Used for Novel/Familiar Photograph Comparisons in Experiment 2

Novel

Manner Verbs

He danced through the menu.

Bailó por el menú.

Every year some students will limp through their exams.

Todos los años hay algunos estudiantes que cojean por los exámenes.

Whenever you want her attention, she's always sliding through the clouds.

Cada vez que quieres su atención, siempre se desliza por las nubes.

I mostly swung between a rockstar and a nerd during my twenties.

La mayor parte de mis veintes columpiaba entre un rockstar y un nerdo.

We wandered through the magazine.

Vagamos por la revista.

Path Verbs

We were circling that movie for hours.

Rodeábamos varias horas alrededor de la película.

I crossed into politics by way of law.
 Cruzé a la política por ruta de la abogacía.
 It was hoped that lowering taxes would advance the economy.
 Se esperaba que bajar impuestos avanzaría la economía.
 While I was waiting for the results, I sank to the floor.
 Mientras esperaba los resultados, me hundí al piso.
 She managed to distance school from home.
 Ella consiguió distanciar la escuela de la casa.

Familiar

Manner Verbs

You are walking a fine line between love and hate.
 Estás trazando una delgada línea entre el amor y el odio.
 * I can't seem to escape this bad mood.
 * No me puedo zafar de este mal humor.
 * He broke up with her yesterday.
 * Él la tronó ayer.
 She dragged me into it.
 Ella me arrastró a eso.
 * The concept hit me like a brick wall.
 * La sola idea me impactó como una pared de ladrillos.

Path Verbs

All that hard work went out the window.
 Todo el trabajo se fue por la ventana.
 I entered into a new stage in life.
 He entrado a una nueva etapa de mi vida.
 He got lost in deep thought.
 Se perdió en sus profundos pensamientos.
 The information went in one ear and went out the other.
 Le entró por un oído y le salió por el otro.
 That policy has yet to be set in motion.
 Todavía tiene que ponerse en marcha la iniciativa de ley.
 * These sentences were eliminated from analyses due to Mexican dialect in familiar metaphors

Chapter 79

CULTURE IN EMBODIMENT: EVIDENCE FROM CONCEPTUAL METAPHORS/METONYMIES OF ANGER IN AKAN AND ENGLISH

Gladys Nyarko Ansah

University of Ghana, Legon, Ghana

ABSTRACT

This paper compares and contrasts the metaphoric/metonymic conceptualisations of ANGER in English and Akan, a West African, Kwa, language within the general framework of conceptual metaphor theory (CMT). Studies on cross-cultural conceptual metaphors/metonymies in the cognitive linguistic tradition, particularly, those that concern emotion concepts, reveal both similarities and variation. The cultural embodied prototype theory (Kövecses 2000, 2005; Maalej 1999, 2004) explains this phenomenon by positing the cultural embodiment hypothesis. The paper particularly focuses on the language-specific construals or elaborations of shared conceptual metaphors of ANGER in the two languages to argue in support of the cultural embodiment hypothesis, namely that embodied cognition (as is reflected in the metaphorical/metonymic conceptualisations of emotions) is based on both universal human experience and culture-specific experience. The linguistic evidence in this paper suggests that universal human embodied cognition works only at the generic/highly schematic level of conceptualisation. However, they are given language-specific elaborations or construals that are grounded in cultural salience (cultural embodiment). Using both primary and secondary data, this paper contributes to the universality versus language-specificity of emotion conceptualisation debate by bringing evidence from a less known language/culture.

Keywords: conceptual metaphor/metonymy, emotions, variation, cultural embodiment, cultural salience

ABBREVIATIONS

Compl - Completive Aspect
 Det. - Determiner
 Nom. - Nominal Marker/Morpheme
 Neg. - Negative Marker/Morpheme
 Prog. - Progressive Marker
 Plu. - Plural marker
 Rel. - Relative Marker
 Redup - Reduplicated form/reduplication
 1SG - First person singular pronoun
 2SG - Second person singular pronoun
 3SG - Third person singular pronoun
 1PL - First person plural pronoun
 2PL - Second person plural pronoun
 3PL - Third person plural pronoun

1. INTRODUCTION

The question of whether the conceptualisations of human emotions are universal across cultures or language/culture-specific has been a matter of research interest in cognitive linguistics and social anthropology (Lakoff and Johnson 1980; Lakoff 1987; Lutz 1988; Kövecses 2000, 2005; Maleej 2004). Several views and positions that have been expressed in this regard centred around two main competing arguments. The first argument is that the conceptualisations of basic human emotions, e.g., ‘anger’ and ‘love’ are universal, i.e., the same across cultures because they are grounded in universal human experience (embodied cognition). The second line of argument in this debate holds that the conceptualisations of emotions are culture-specific because they are socio-culturally constructed. Based on more recent findings from cross-cultural studies on the conceptualisations of basic human emotions, however, there is a third emerging argument, the cultural embodied prototype hypothesis (Kövecses 2005; Maalej, 2004), which takes the middle position that the conceptualisation of human emotions across cultures may be universal and culture-specific at the same time. Its proponents explain how this is possible by suggesting an extended view of the embodied cognition thesis, i.e., the cultural embodied cognition thesis (Kövecses 2005; Maalej, 2004).

The paper examines the influence of culture in the metaphorical/metonymic conceptualisations of anger, a primary emotion, in Akan and English. It focuses particularly on the differences and/or similarities in the language-specific realisations/elaborations of shared conceptual metaphors/metonymies of anger in the two languages. The analysis of the language-specific realisations of the metaphoric/metonymic conceptualisations of anger in the two languages reveals both similarities and differences. Consequently, in line with the cultural embodied cognition thesis, the paper concludes that while the similarities in the language-specific elaborations in the two languages may be attributed to universal embodied cognition from which general metaphorical principles derive, the differences in language-

specific construals/elaborations may be explained in terms of cultural filtering. In other words, whereas the shared conceptualisations may reflect general universal human experiences, the language-specific construals/elaborations may reflect experiences that are more salient to a particular socio-cultural group. As Lutz (1988) has argued, universal embodiment may be overridden by cultural factors.

Although evidence for the various debates has come from many different languages and cultures, only a couple of such evidence has come from African languages and cultures (Taylor and Mbense 1998). This paper, therefore, comes as a contribution to the universality versus culture-specificity debate by bringing evidence from another less known language/culture.

2. CONCEPTUALISING EMOTIONS ACROSS CULTURES: THE UNIVERSAL VS CULTURE-SPECIFIC DEBATE

The existence of major similarities and variations in the conceptualisations of basic emotion concepts within and between cultures has been documented extensively in cognitive linguistic research and social anthropology (Breugelmans et al. 2005; King 1989; Kövecses 2000, 2005; Lutz 1988; Taylor and Mbense 1998; Yu 1995). Often discussed in terms of conceptual metaphors, the similarities of conceptualisation of emotion concepts across cultures have been explained in terms of the embodied cognition thesis. First introduced by Lakoff and Johnson (1980) in what has become known as the standard view, it was proposed that conceptual metaphors in general are based on human embodied cognition, i.e., how the human body and brain function in relation to their environment. Subsequently, universal human experiences, including human emotions, produce universal conceptual metaphors. The embodied cognition thesis became the basis for the prototype view which regards emotion concepts as structured scripts, scenarios or cognitive models.

The experientialists within the prototype view (e.g., Lakoff 1987) subscribe fully to the embodied cognition thesis and posit that emotion concepts that have prototypical emotion scripts, and therefore their conceptualisations are largely universal, i.e., are likely to be the same or near universal across languages and cultures because such conceptualisations are based largely on universal human experiences, e.g., getting angry and a rise in bodily temperature. However, the social constructionists within this view, while agreeing with the notion that emotion concepts are scripts/scenarios, disagree with the experientialists' claim that the conceptualisations of such scripts are the same across cultures.

The social constructionists argue that emotion concepts are socio-cultural scripts/scenarios or constructs whose properties depend on particular aspects of a given culture. Consequently, different cultures are likely to have different conceptualisations for the same emotion concepts because different cultures give concepts different socio-cultural salience.

The embodied cultural prototype view (Kövecses 2000, 2005; Maleej 2004) synthesises the two diverging prototype views and proposes that the conceptualisation of emotion scripts across cultures is based on both universal human embodied experiences and more specific socio-cultural constructions. These theorists argue that while social constructions have a bodily basis, bodily motivations have a socio-cultural salience, i.e., the general

conceptualisation of basic human emotion concepts may be grounded in universal human experiences. However, different cultures appear to attach different cultural salience to such experiences which reflects in specific realisations, elaborations or construals of these near-universal conceptualisations.

According to Kövecses (2000, 2005), these similarities and variations in the cross-cultural conceptualisation of emotions occur in two major areas: (1) the source domains in terms of which a particular target concept is understood, and (2) the elaborations in the conceptual correspondences of shared conceptual metaphors. This paper focuses on the latter.

3. METHODS

The paper adopts conceptual metaphor theory (CMT) framework of metaphor analysis (Lakoff and Johnson 1080; Lakoff 1987; Kövecses 2000, 2002). First proposed by Lakoff and Johnson (1980), CMT claims that ‘the generalizations governing metaphorical language are not in language, but in thought: they are general mappings across conceptual domains’ (Lakoff 1993:1). In other words, CMT posits that metaphor is primarily a conceptual phenomenon and only derivatively linguistic. In CMT, metaphor is generally defined as using the knowledge structure of a more concrete domain of experience (source domain) to understand a less concrete, more abstract one (target domain).

Under the assumption that language is a window onto cognition (i.e., linguistic expressions in part reflect cognitive processes and structures), CMT further proposes that linguistic metaphors which are instantiations of conceptual metaphors are a good evidence of what our conceptual system looks like. Consequently, CMT researchers systematically infer conceptual representations and organisation from linguistic expressions that are metaphorically understood by positing conceptual mappings between two conceptual domains, a source domain and a target domain. For example, based on the metaphorical expressions (in italics) about social organisation in English in examples 1a-e below, Kövecses (2002) suggests that the knowledge structure of PLANTS is used to understand SOCIAL ORGANISATIONS in English. He postulates the following conceptual correspondences as licensing the linguistic metaphors in 1a-e:

Table 1. Conceptual correspondences for the SOCIAL ORGANISATIONS ARE PLANTS metaphor

Source: Plant		Target: Social organization
The whole plant	⇒	the entire organization
A part of the plant	⇒	a part of the organization
Growth of the plant	⇒	development of the organization
Removing a part of the plant	⇒	reducing the organization
The root of the plant	⇒	the origin of the organization
The flowering	⇒	the best stage, the most successful stage
The fruit or crops	⇒	the beneficial consequences

(1) SOCIAL ORGANISATIONS ARE PLANTS

- (a) *He works for the local branch of the bank.*
- (b) *Our company is growing.*
- (c) *They had to prune the workforce.*
- (d) *The organization was rooted in the old church.*
- (e) *His business blossomed (Kövecses (2002: 8)).*

In this paper, two sets of linguistic data, (native English data and native Akan data) were analysed. The English data were collated from secondary sources, i.e., based on previously analysed conceptual metaphors in English (Esenova 2009; Kövecses 2000, 2005; Lakoff 1987). However, the Akan data were primary data, elicited through focus group discussions. Relatively monolingual¹ native speakers of Akan in rural and semi-rural Ghana participated in focus group discussions to generate linguistic expressions that are conventionally used to talk about anger in Akan and from which conceptual metaphors of anger in Akan were extracted for analysis. A short video that aimed to depict and evoke anger (and fear)² was used as a stimulus for the elicitation. Each focus group was constituted by between 6-8 participants and each discussion lasted for approximately 12 minutes. In all a total of approximately 120 minutes of discussions were audio recorded and later transcribed for analysis.

In identifying linguistic metaphors, I adopted the MIP approach. In formulating conceptual metaphors, while the model provided in the literature was a helpful guide, I opted a bottom-up approach, i.e., I stayed as close as possible to the actual words/phrases in the data. I also relied on the broader context of the elicitation in interpreting a particular metaphorical expression and in establishing metaphorical connections between two conceptual domains. The patterns that emerged from the data were captured in terms of a formulation of hypotheses about cross-domain mappings. These formulated hypotheses I refer to as conceptual metaphors (presented in small caps in line with conceptual metaphor theory tradition). In the discussion of my examples, I maintain the original Akan metaphorical expressions and then provide three levels of translation for them, namely, an interlinear glossing, a literal translation and an English translation equivalent where possible.

4. CONCEPTUAL METAPHORS AND EMOTION CONCEPTS

Recent research in cognitive science has paid particular attention to the study of emotion concepts, particularly the language of emotion concepts (Kövecses 1990, 2000, 2005) although in the past emotions were traditionally regarded in psychology as extras not as serious mental functions like perception, language, thinking and learning’.

¹ Ghana is a highly multilingual country (ethnologue (2009) records 79 indigenous languages plus English and other West African trade/border languages, e.g. French and Hausa). Nevertheless, Akan enjoys a high level of language vitality; about 50% of Ghana’s population are native Akan speakers and about 44% of the population speaking it as a second or vehicular language. Consequently, many native Akan speakers especially in rural native Akan speaking communities are largely monolingual even though they may know a word or two from other languages.

² The original study from which this paper is taken discussed the metaphorical/metonymic conceptualisation of anger and fear among three groups of people: native English speakers, native Akan speakers and Akan-English bilingual speakers in Ghana.

In semantics, emotion concepts were considered as consisting of feelings only and devoid of conceptual content (Lakoff 1987). However, current researchers recognise the important contribution findings from the study of emotion concepts can make to research on cognition. Similarly, Lakoff (1987:380) submits that ‘emotions have an extremely complex structure, which gives rise to a wide variety of non-trivial inferences’.

Cognitive linguistic research on emotion concepts, especially in the conceptual metaphor theory (CMT) tradition, has focused largely on the conceptual structure of such concepts as well as the language used to describe them within and across cultures. Thus, CMT researchers investigate the conceptualisation of emotion concepts by inferring the conceptual structures of the concepts from a careful study and analysis of the metaphorical expressions that are used to talk about them. While the study of emotion concepts and the language of emotion concepts has been studied extensively in English, Dzokoto and Okazaki (2006) is the most frequently cited study of the language of emotion in Akan.

5. METAPHORS OF ANGER IN ENGLISH

The study of the conceptual structure of anger as an emotion concept has received a lot of research attention in cognitive linguistics following the pioneering works of Lakoff (1987), Lakoff and Kövecses (1987) and Kövecses (1990) on ANGER in American English.

These studies have been replicated in several other languages including Chinese (Yu 1995), Zulu (Taylor and Mbense 1998), Spanish (Soriano 2003) and Tunis-Arabic (Maalej 1999, 2004). Different but complementary methodological approaches, including the CMT approach (Lakoff 1987, Lakoff; Kövecses 1987, Kövecses 1990, 2002), corpus linguistics approaches (Esenova 2009), and discourse approaches (Lutz 1988), have been employed in these studies. Consequently, I rely on previously analysed data and present a brief overview of the conventional conceptual metaphors/metonymies of anger in English particularly as discussed in Esenova (2009), Lakoff (1987) and Kövecses (2002).

Lakoff (1987), Lakoff and Kövecses (1987) and Kövecses (2002) have proposed that the conceptual structure of ANGER in English consists of a system of conceptual metaphors that derive from general metonymic and metaphoric principles. First of all, they postulate that the metonymic conceptualisations of ANGER in English are motivated by the folk understandings of the physiological effects of anger on the angry person in English.

The central metonymic principle underlying such conceptualisations is: THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION. Based on this central metonymy, Lakoff (1987) postulates the following system of metonymies of anger in English:

BODY HEAT IS ANGER: He is a *hothead*.

INTERNAL PRESSURE IS ANGER: He almost *burst a blood vessel*.

(COLOUR OF SKIN) REDNESS IN FACE AND NECK AREA IS ANGER: He *got red with anger*.

PHYSICAL AGITATION IS ANGER: He's *all worked up*.

INTERFERENCE WITH ACCURATE PERCEPTION IS ANGER: She *was blind with rage*.

In the literature, linguistic metaphors/metonymies or metaphorical expressions that are conventionally used to talk about ANGER in English have been systematically pointed to the following conventional conceptual metaphors:

(2) ANGER IS A HOT FLUID IN A CONTAINER:

- (a) *She's a real hothead*³.
- (b) *You make my blood boil.*
- (c) *Let her stew.*
- (d) *I got all steamed up.*
- (e) *He's just blowing off steam.*
- (f) *I had reached the boiling point.*
- (g) *He boiled over.*
- (h) *She felt her gorge rising.*
- (i) *Simmer down!* (Kövecses 2002:96)

(3) ANGRY PERSON IS A PRESSURISED CONTAINER

- (a) *He exploded.*
- (b) *I blew a gasket.*
- (c) *He was fuming.*
- (d) *I could barely keep it in anymore.*
- (e) *He managed to keep his anger bottled up inside him.*
- (f) *He suppressed his anger.*
- (g) *He let out his anger* (Kövecses 2005:39).

(4) ANGER IS FIRE⁴

- (a) *Those were inflammatory remarks.*
- (b) *She was doing a slow burn.*
- (c) *He was breathing fire.*
- (d) *Your insincere apology just added fuel to the fire.*
- (e) *After the argument, Dave was smoldering for days.*
- (f) *Boy, am I burned up.*
- (g) *He was consumed by his anger* (Lakoff 1987:388).

(5) ANGER IS INSANITY⁵

- (a) *I just touched him, and he went crazy.*
- (b) *You're driving me nuts!*
- (c) *One more complaint and I'll go berserk.*
- (d) *He got so angry he went out of his mind.*
- (e) *She went into an insane rage.*

³ Hothead is an example of the interaction between metaphor and metonymy in the conceptualisation of ANGER in English.

⁴ Lakoff (1987) suggests that this metaphor derives from combining aspects of the BODY IS A CONTAINER FOR THE EMOTIONS metaphor, the metonymic conceptualisation of anger in terms of REDNESS IN THE FACE AND NECK AREA and the metaphonymy ANGER IS HEAT (when heat is applied to solids).

⁵ Interestingly, what looks like the most frequently used linguistic instantiation of this metaphor, *to be mad*, e.g. *I am mad at you*, in American English was absent from Lakoff's list above.

- (f) *If anything else goes wrong, I'll get hysterical.*
 (g) *He's fit to be tied.*
 (h) *He's about to throw a tantrum (Lakoff 1987:390).*

(6) **ANGER IS AN OPPONENT (IN A STRUGGLE)⁶**

- (a) *I'm struggling with my anger.*
 (b) *He was battling his anger.*
 (c) *She fought back her anger.*
 (d) *You need to subdue your anger.*
 (e) *I've been wrestling with my anger all day.*
 (f) *I was seized by anger.*
 (g) *He lost control over his anger.*
 (h) *Anger took control of him.*
 (i) *He surrendered to his anger.*
 (j) *He was overcome by anger (Lakoff 1987:391).*

(7) **ANGER IS A DANGEROUS ANIMAL⁷:**

- (a) *He has a monstrous anger.*
 (b) *He has a fierce temper.*
 (c) *He has a ferocious temper.*
 (d) *He unleashed his anger.*
 (e) *His anger is insatiable (Lakoff 1987:392-3).*

Table 2. Conceptual correspondences licensing the ANGER IS A DANGEROUS ANIMAL metaphor

Source: dangerous Animal		Target: Anger
The animal getting loose	⇒	loss of control of anger
The owner of the dangerous animal	⇒	the angry person
Energy needed to control a dangerous animal	⇒	energy needed to control anger

The mappings in this metaphor appear to be based on source domain entailments only rather than source domain lexis. In other words, while the metaphorically used words may implicitly suggest references to some animal behaviour or feature, they are not typical lexis of the source domain; they may be applicable to other source domains, e.g., *insatiable* may be applicable to a person.

⁶ This metaphor is believed to be motivated by the general understanding of the difficulty involved in the angry person controlling the undesirable reactions anger produces, i.e. the effort one needs to control the negative/undesirable reactions anger produces is metaphorically understood in terms of the effort one needs to engage in a struggle with an opponent.

⁷ Lakoff (1987:392-3) suggests that this metaphor is motivated by the perceived potential danger of anger in relation to other people around the angry person which is said to be conceptualised in terms of 'a sleeping animal that is dangerous to awaken, something that can grow and become dangerous, as something that has to be held back, and as something with a dangerous appetite'. He proposes the conceptual correspondences in table 2 above as licensing the linguistic metaphors in example (7) above:

However, it is interesting to note that insatiable people are often perceived as greedy people and greedy people are often perceived as some kind of animal. For instance, in English, a greedy or gluttonous person is referred to as a *pig*.

Nevertheless, the linguistic expressions that have been postulated as instantiations of this metaphor may refer to entities other than an animal.

This is an example of instances where some claims in conceptual metaphor theory, particularly, the up-down approach to the formulation of conceptual metaphors appear problematic.

(8) *ANGER IS A HORSE*⁸

- (a) *His common sense is a bridle to his quick temper.*
- (b) *I usually manage to curb my anger when I am at home, but at work I often don't succeed.*
- (c) *However, it will pay you to curb your famous temper.*
- (d) *Scipio bridled his indignation.*
- (e) *Burun was unable to rein in his temper (Esenova 2009: 4.2).*

(9) *ANGER IS A PLANT*

- (a) *After this, depression sets in and deep seated anger can take root.*
- (b) *The feeling of rejection had quickly blossomed into anger.*
- (c) *Divorce is too often the bitter fruit of anger.*
- (d) *Anger is rooted in our survival instincts and has a legitimate and vital function in human behavior (Esenova 2009:4.2).*

(10) *ANGER IS A BURDEN*

- (a) *Unburdening himself of his anger gave him a sense of relief.*
- (b) *He carries his anger around with him.*
- (c) *After I lost my anger, I felt lighter.*
- (d) *He has a chip in his shoulder.*
- (e) *You'll feel better if you get it off your chest (Lakoff 1987:396).*

(11) *ANGER IS A STORM*

- (a) *It was a stormy meeting.*
He stormed out of the meeting.

(12) *ANGER IS A CHILD*

- (a) *Say, shall we nurse the rage?*
- (b) *Instead he decided to nurse his anger.*
- (c) *He nurtured that anger for a decade.*
- (d) *Fostering anger over a long enough time can lead to violence.*
- (e) *Anger begets anger, which leads to conflicts (Esenova 2009: 4.2).*

⁸ This may be regarded as a more specific realization of the *ANGER IS A DANGEROUS ANIMAL* metaphor.

Based on evidence of conventional linguistic metaphors of anger that are believed to instantiate underlying metaphorical conceptualisations, it has been suggested that the prototypical ANGER scenario in English has five stages:

- Stage 1: Offending event
 - Stage 2: Anger exists
 - Stage 3: Attempt to control anger
 - Stage 4: Loss of control (anger controls)
 - Stage 5: Retribution (angry behaviour)
- (Holland and Quinn 1987: 214).

6. METAPHORS OF ANGER IN AKAN

Studies on emotion concepts in Akan in general are scanty. Except for Dzokoto and Okazaki (2006), who have examined (in part) the folk emotion lexicon in Fante, a major dialect of Akan, I do not know any research on this topic in Akan. With specific regards to anger, the only known works in the cognitive tradition are Ansah (2008, 2011).

The concept of ANGER appears deeply entrenched in Akan. It is lexicalised as *Abufu/abufuw/abufuo*⁹ in the language. The word *abufuw* is multimorphemic, consisting of the following morphemes: *a-* (a nominal marker) *bo*¹⁰ - (chest), *fuw* (to grow weed)¹¹. Even before I introduced the word *abufuw* in the focus group discussions, the participants used it frequently to either denote anger or describe angry situations.

Like English, the conceptualisations of anger in Akan are motivated by both general metonymic and metaphorical principles. For example, it is clear from the context that the phrases that contain the word *abufuw* denote the concept of anger or describe angry situations are metaphorical, denoting anger rather than the literal or more basic meaning of a chest growing weed. Indeed, there would be a semantic clash if their more basic meanings were assumed. However, we can understand the development of anger or the process of getting angry in Akan metaphorically in terms of the process of weed growing. I discuss the Akan conceptualisation of anger in terms of growing weed in detail later. Another source of evidence of metaphorisation in the conceptualisations of anger in Akan is found in the use of the human body container schema in the lexicalised form of the concept of anger in Akan - where the chest is a container for anger.

Secondly, like English, there is a system of conceptual metonymies of anger in Akan where the folk understandings of the physiological effects of anger in Akan stand for anger:

⁹ These are the phonetic realisations in the three major dialects, Fante, Akuapem and Asante respectively. In this study, I shall stick to the unified Akan orthographic form, *abufuw*.

¹⁰ The vowel change is due to +ATR assimilation or harmonisation.

¹¹ Even though this verb is applicable to other instances of growth, e.g. hair growth, I would like to argue that to grow weed is a more basic sense, and to grow hair a metaphorical extension of this sense. For instance, overly grown hair is described in terms of a forest in Akan. In addition, for *fuw* to apply to hair growth on the chest, it will require the use of the adposition *so* 'on' after *bo* 'chest'. For example, *ne bo so afuw* 'his/her chest is hairy'. Finally, *fuw* does not apply in other instances of growth such as the growth of a human being or non-weed plants. The verb that designates this kind of general growth is *nyin(i)*.

BODY HEAT IS ANGER: ne bo rehye ‘his/her chest is *burning*’; ne bo rehuru so ‘his/her chest is *boiling over*’ (he/she is boiling with anger).

INTERNAL PRESSURE IS ANGER: ɔrepae ‘he/she is *splitting open*’ (he/she is bursting with anger).

BODY PART STANDS FOR ANGER: ne bo fuw ‘his/her *chest* grows weed’; n’atiko apae ‘the *back of his/her head* has split open’.

However, unlike in English, there is no linguistic evidence to suggest that any of the conceptual metonymies of anger in Akan are motivated by the physiological effects of anger relating to a change in skin colour (redness) around the neck and face area. Thus, we may suggest that conceptualisations of anger in Akan are equally constituted by a system of conceptual metaphors that are based on general metonymic and metaphorical principles.

Based on a range of conventional metaphorical expressions used by the native Akan participants to describe different aspects of anger, the following conventional conceptual metaphors of the emotion in Akan were inferred. Here I provide the conceptual correspondences (in a table form) that license the various linguistic metaphors.

Table 3. Conceptual correspondences for ANGER IS A GROWING WEED metaphor

Source: A growing weed		Target: Anger
Weed	⇒	Anger
The process of the weed growing	⇒	the process of getting angry
The place for growing weed	⇒	the angry person’s body/chest
What causes the weed to grow	⇒	what causes the anger
Frequency of weed growth	⇒	frequency of occurrence of anger

(13) ANGER IS GROWING WEED:

(a) Me-bo a-fuw.

Me-chest COMPL- grow weed.

My chest is has grown weed/ is bushy.

I am angry.

(b) Ne bo n-kyere fuw.

3SG chest Neg-long grow weed.

His/her chest does not take long to grow weed.

He/she is quick tempered.

(c) Ne bo fuw ntem-ntem.

3SG chest grow weed quick-redup.

His/her chest grows weed quickly.

He/she is quick tempered.

It may be argued that the ANGER IS A GROWING WEED metaphor constitutes what Semino (2010:2) calls an unrealistic scenario, i.e., implausible, counterintuitive, absurd, or impossible scenario – a scenario which does not reflect what people already know about the source domain. Typically, weeds do not grow on chests. However, contrary to Semino's examples where the metaphors that evoked these unrealistic scenarios were on-line constructions or creative metaphors, the ANGER IS A GROWING WEED metaphor is highly conventional in Akan, perhaps the most conventionalised metaphorical conceptualisation of anger in Akan.

Table 4. The conceptual mappings I propose for the ANGER IS A HOT FLUID IN A CONTAINER metaphor

<i>Source: Hot fluid in a container</i>		<i>Target: Anger</i>
The physical container	⇒	the angry person's body
The hot fluid inside the container	⇒	the anger
The degree of fluid heat	⇒	the intensity of anger
The cause of increase in fluid heat	⇒	the cause of anger

(14) ANGER IS A HOT FLUID IN A CONATINER

(a) Ne bo re huru so.

Poss-chest prog.boil over

His/her chest is boiling over.

He/she is boiling with anger.

(b) Ne bo n-nwo ne ho.

Poss-chest neg-cool poss. self

His/her chest does not cool itself/himself/herself.

He/she is angry.

(c) ɔ-wɔ a-bu-fuw hyew.

3SG-possess nom-chest-weedy hot.

He/she has a hot, weedy chest.

He is hot tempered.

(d) Nebo n-now-e. ‘

Poss chest neg-cool-past

His/her chest has not cooled down.

He/she is not appeased.

Like English, Akan also makes use of some entailment potentials of the body container source domain to elaborate the ANGER IS A HOT FLUID IN A CONTAINER metaphor. For instance, the general knowledge that intense heat causes a rise in volume or upward movement of a fluid in a container corresponds to the increase in the intensity of anger in Akan where the entire container rather than the hot fluid in it moves upward, e.g., *n'akoma a-sɔre* 'his/her heart has risen'; *n'akoma kɔ soro* 'his/her heart has gone up'; *nebo rehuru* 'his chest is boiling'. Another carryover knowledge from the source domain that produces metaphorical entailments in the Akan mapping is that too much heat can cause the container

to explode and that when the container explodes, what was inside it comes out, e.g., *w'adwa* 'he has split open'; *ɔrepae* 'he/she is bursting/breaking'.

However, while some elaborations of the English mapping are based on the entailment potential 'hot fluid produces steam in the container', e.g., *He's just letting off steam*; there is no linguistic evidence of such elaborations in Akan. Again, there is linguistic evidence to show that the entailment that in the case of an explosion parts of the container go up in the air, and what was inside the container comes out. However, there is no linguistic evidence to suggest that parts of the Akan body container go up in the air in the case of explosion even though there are some linguistic elaborations based on the entailment that in an explosion what was inside the container comes out as shown in the following example from the focus group discussions:

(15)

(a) *Mebofu a mentumi nyɛ hwee, enti sɛ me ne nipa no ko a na abufuo no afiri me mu.*

When I get angry I can't do anything so if I fight the person, then the anger gets out of me.

Indeed, the conceptualisation of ANGER AS A HOT FLUID IN A CONTAINER is consistent with the conceptualisation of *abotare* 'patience', an emotion concept in Akan that stands in direct opposition to anger, as A COLD FLUID IN A CONTAINER. Lakoff (1987) has suggested that in the ANGER IS A HOT FLUID IN A CONTAINER metaphor, when there is no heat, the fluid is cool and calm and that this coolness and calmness corresponds to lack of anger in the central metaphonymy ANGER IS HEAT. For example, while hot fluids have the tendency to rise in volume and get out of their containers, cool or cooled substances have the tendency or propensity to settle or remain securely in their containers, contrasting with the hot fluids causing a rise in volume entailment in the ANGER IS A HOT FLUID IN A CONTAINER metaphor. Thus, *abotare* 'patience' (the process of a chest sticking to) is conceptualised as A COOL/COLD FLUID IN A CONTAINER in Akan. As the concept that most closely contrasts *abufuw* 'anger' in Akan, the metaphorical conceptualisation of *abotare* 'patience' is consistent with the metaphorical conceptualisation of anger in the language.

(16) PATIENCE IS A COLD FLUID IN A CONTAINER

(a) *Me-bo a-dwo.*

Me-chest COMPL-cooled down

My chest has cooled down.

I am not angry any more.

(b) *Me-bo a-tɔ me-yam.*

Poss-chest COMPL-fall poss-stomach

My chest has fallen into my stomach.

I am appeased.

(c) *N'-akoma a-tɔ ne-yam.*

Poss-heart COMPL-fall poss-stomach

His/her heart has fallen into his/her stomach.

He/she has calmed down.

The linguistic data revealed what may be classified as the two prototypical models of anger in Akan:

Model 1:

Stage 1: Offending event

Stage 2: Anger exists

Stage 3: Control

Model 2:¹²

Stage 1: Offending event

Stage 2: Anger exists

Stage 3: Retribution

For instance, on the question of how participants react, in terms of what they typically do to people who make them angry and what they gain from doing such things, two main responses emerged: (1) refraining from taking action against the offending people and (2) taking action against the offending people. Even though participants in both categories described anger as a negative and potentially dangerous emotion, each group identified different entities as the target of the potential danger of anger. On the one hand, the participants who refrain from taking any action argued that anger is dangerous to people other than the angry person. Subsequently, any action that is taken in anger could be dangerous not only to the source of the anger, the offending party but also other people around. Therefore, anger must be *tamed*, *controlled* and *not let loose*. For such speakers of Akan therefore, anger is a dangerous thing that must be controlled.

Table 5. My proposed conceptual mappings for the Akan version of the ANGER IS A DANGEROUS ANIMAL metaphor

<i>Source: Dangerous thing</i>		<i>Target: Anger</i>
The thing being let loose	⇒	loss of control of anger
The owner of the dangerous thing	⇒	the angry person
Energy needed to control a dangerous thing	⇒	energy needed to control anger

(17) ANGER IS A DANGEROUS THING

(a) *Sɛ mebo fuw a meyɛ dinn efiri sɛ ɛwɔ sɛ wotumi kontro¹³/hyɛ abufuw no so.*

When I get angry I keep quiet because one has to be able to control the anger.

I keep calm when I am angry in order to control the anger.

On the other hand, the second group of native Akan participants identified the angry person as the target of the potential danger of the emotion of anger, i.e., that unexpressed anger is dangerous to the angry person's body and mind. For such speakers of Akan, anger is

¹² This model may explain why anger is not metaphorically conceptualised as AN OPPONENT IN A STRUGGLE in native Akan.

¹³ This participant actually used the Akan version of the English word 'control' as well as the Akan equivalent of that word *hyɛ so* 'suppress'. This is an example of lexical borrowing in Akan.

conceptualised either as a burden (for the angry person who has to control (bear) it) or a disease that has to be released or removed from the angry person's body container in one way or another in order to restore the body container to its normal condition.

Table 6. Mappings for the Akan version of ANGER IS A BURDEN

Source: Burden		Target: Anger
The burden bearer	⇒	the angry person
The burden	⇒	Anger
Carrying the burden	⇒	keeping/suppressing the anger
Offloading the burden/unburdening	⇒	expressing anger

(18) ANGER IS A BURDEN

(a) *Mebofu a na aye se biribi hye me so; mentumi nye frii*

When I get angry it is like something is weighing me down; I can't be free.

(b) *Obi hye me abufu a meka foo kyere no na deɛ ehye me so no afiri me mu.*

When someone makes me angry I say nasty things to them to let that which weighs me down get out of me.

(c) *Se obi hye me abufuo a mene no ko; mene no ko wie a na abufuo no afiri me mu.*

When someone makes me angry I fight them. When I fight them the anger leaves me.

(d) *Mebofu a mekasa-kasa se nye saa a m'akoma nto me yam.*

When I am angry I talk repeatedly if not my heart won't fall into my stomach.

When I get angry I vent my anger verbally in order to be appeased.

(e) *Me bofu a na aye se biribi hye me so; mentumi nye frii¹⁴*

When I get angry it is like something is weighing me down; I can't be free.

(19) ANGER IS A DISEASE

(a) *Obi ye na mebofu a, metumi a mebo no na meho atɔ me.*

If someone makes me angry, if I can I beat them up and recover.

(b) *Se obi hye me abufuw na medidi n'atem a na meho atɔ me.*

When someone makes me angry and I insult the person I recover

Table 7. Mappings for the Akan version of ANGER IS A DISEASE

Source: Disease		Target: Anger
Disease causing agent	⇒	the cause of anger
The disease	⇒	Anger
Curing the disease	⇒	expressing anger
Recovering from disease	⇒	relief from anger

While the Akan conceptualisation of the potential danger of anger in relation to the angry person is akin to the retribution stage of the prototypical anger scenario in English, it is

¹⁴ This is another instance of borrowing from English 'free'.

important to mention that stages 3 and 4 of the prototypical anger scenario in English may be of no consequences at all in what appears to be the prototypical anger scenarios in Akan.

(20) *ANGER IS FOOD*¹⁵

(a) *Asem no a-mee*¹⁶ *me*

Matter DET COMPL-full up me

I am full up with the matter.

I am fed up/I am angry.

(b) *Asem no me-e no boro- o so.*

Matter Det. Full- past 3SG more- past on.

The matter made him (the man in the video) overly full up.

The man was fed up with the matter (the woman's behaviour).

(c) *Me mene m'abufuw nyinaa nam' ano ankɔpa.*

ISG swallow Poss-anger all CONJ. Poss mouth neg. go slip.

I swallow all my anger so my mouth does not slip (i.e., do not say the wrong things).

Table 8. Mappings for the Akan version of ANGER IS FOOD

Source: Food		Target: Anger
Food /matter	⇒	Anger
Swallowing food	⇒	controlling anger
Taste of the food	⇒	the cause of anger

7. DIFFERENCES AND/OR SIMILARITIES BETWEEN ENGLISH AND AKAN CONCEPTUALISATIONS OF ANGER

The analyses above have pointed to both similarities and differences with regards to source domains in the conceptualisations of anger in Akan and English. First of all, both English and Akan speakers make use of general metonymic and metaphoric principles in their conceptualisations of anger. The two languages shared the following generic-level conceptual metonymies/metaphors from which more specific metonymies/metaphors of anger were derived: BODY HEAT STANDS FOR ANGER, THE HUMAN BODY IS A CONTAINER FOR THE EMOTIONS and EMOTION IS A GROWING THING. Indeed, the HUAMN BODY AS A CONTAINER was a key source domain for both metonymic and metaphorical conceptualisations of anger in both languages.

For instance, the physiological effects of anger on the body are used metonymically in both languages to stand for the emotion, e.g., BODY HEAT IS ANGER, INTERNAL PRESSURE IS ANGER etc. Nevertheless, not all the physiological effects identified in English were also used in Akan. For example, whereas agitation and skin colour (redness

¹⁵ Among the participants who considered anger as dangerous to other people, controlling anger was described in terms of the Akan word mene 'to swallow'.

¹⁶ While the translation equivalent may not exactly express anger in English, in the context, the Akan expression denotes implicit anger.

around the face and neck area) are used metonymically to conceptualise anger in English, these physiological effects of anger are not used in the conceptualisation of the emotion in Akan. Other source domains shared between the two languages are: A BURDEN and A HOT FLUID IN A CONTAINER. Nevertheless, there were source domains that were exclusive to each language: A NATURAL FORCE, AN OPPONENT IN A STRUGGLE, INSANITY, FIRE and A CHILD (English) and A DISEASE and FOOD (Akan).

As the literature suggests, variation in the conceptualisation of emotions across languages/cultures may show in how each language/culture actually construes the shared source domains. For example, Kövecses (2000) reports that American English and Chinese share a common source domain SPORT in their metaphoric understanding of POLITICS. However, SPORT is specifically construed as *American football* and *baseball* in American English, on the one hand and as *table tennis*, *volleyball* or *soccer* in Chinese on the other hand. In other words, what is shared between these two languages/cultures appears to be fairly abstract; the language-specific understandings or construals are based on cultural salience, i.e., the popularity of a particular sport in the given culture.

Although the human body is conceptualised as a container for anger in Akan and English, there are differences in the specific body parts that are conceptualised as containing anger in each language. In English anger may be contained in the ‘eyes’, ‘face’, ‘neck’, ‘chest’, ‘guts’, ‘nerves’ and ‘blood’. However, in Akan, anger is metaphorically contained in the ‘chest’, ‘heart’, ‘back of the head’, ‘stomach’ or even the whole body. Secondly, the conceptual metaphor ANGER IS A HOT FLUID IN A CONTAINER occurs in both languages. Nevertheless, there are differences in elaborations of shared mappings. For example, in both languages, the hot fluid corresponds to anger. However, in the elaborations, the hot fluid is specified as ‘blood’ in English (*you make my blood boil*) but the fluid is not specified in Akan. In fact, on the surface it may even look like there is no fluid at all in the Akan conceptualisation because no specific fluid is mentioned in the elaboration. The use of a verb like *huru* ‘to boil’ (*ne bo rehuru* so ‘his/her chest is boiling over’, i.e., he/she is angry), in Akan, however, presupposes the presence of some liquid, usually water, even though other liquids may apply.

In addition, the English elaborations of ANGER IS A HOT FLUID IN A CONTAINER metaphor specify the English body container as covered so that when the loss of control over anger is conceptualised as an explosion, the cover of the English body container may go off in the explosion, e.g., I blew my *top*; He blew the *gasket*¹⁷. However, even though the idea of explosion is alluded to in the Akan elaborations of this metaphor (*wadwa/wapae* ‘he/she has split open’, i.e., he/she has exploded) there is no linguistic evidence to suggest that the Akan body container is covered – no body parts go off in the Akan explosion. The ANGER IS A HOT FLUID IN A CONTAINER metaphor is further elaborated in English based on the entailment potential of the source domain that hot fluid produces steam in the container (He is blowing off *steam*). However, the linguistic evidence does not support this elaboration in Akan conceptualisations even though both languages make use of a related entailment, i.e., too much heat causes too much pressure and too much pressure on the container may lead to the container exploding.

¹⁷ This suggests that anger is conceptualised as a MACHINE in English. This conceptualisation of anger in English is not captured in the literature though.

Again, in the metaphorical entailment of both the English and the Akan conceptualisations of anger as this metaphor, lack of heat corresponds to lack of anger. However, there are differences in the specific ways in which this mapping is elaborated in each language. In English, the body container is made to settle down as a whole (*calm* down). In Akan, however, the specific anger-bearing container is made to settle in a more secure container to either prevent the hot fluid or the anger-bearing container from moving upward. For instance, when one's chest is boiling over (*wobo rehu so* 'be angry') or when one's heart goes up (*w'akoma kɔ soro* 'be angry'), the person may be advised to do one of the following: *ka w'akoma to wo yam* 'push your heart into your stomach' or *ma wo bo ntɔ wo yam* 'let your chest fall into your stomach', both meaning calm down/be patient.

Furthermore, both languages generally conceptualise the process of controlling anger in terms of bearing a BURDEN or controlling A DANGEROUS THING (ANIMAL). However, each language construes this process exclusively in terms of different source domains. On the one hand, English specifically conceptualises the process in terms of struggling with an opponent (he was *battling* his anger). On the other hand, Akan conceptualises the process in terms of eating or swallowing something (*mene w'abufuw* 'swallow your anger', i.e., calm down/be patient). In addition, whereas the linguistic evidence suggests strong implicit connections between the DANGEROUS THING and A DANGEROUS ANIMAL (e.g., a horse) in English, there is no linguistic support for such strong connections in Akan. Finally, the conceptual metaphor ANGER IS A GROWING THING occurs in both languages. However, the GROWING THING is specified in English as A PLANT but as a GROWING WEED in Akan.

CONCLUSION

In this paper, I have compared and contrasted the metaphorical/metonymic conceptualisations of anger in Akan and English. I have particularly focused on the language-specific construals or elaborations of shared conceptualisations between the two languages. The analysis shows support for the culture embodied prototype argument that embodied cognition is both universal and culture-specific, i.e., the metaphorical/metonymic conceptualisations of emotions across cultures are motivated by and grounded in both universal human experiences and culture-specific experiences (Kövecses 2002, 2005, Maalej 1999, 2004). In other words, on the one hand, the similarities between the two languages in terms of source domains and sometimes the similar correspondences in the conceptualisations of anger found in this paper may be interpreted in terms of universal embodied cognition, i.e., the general metaphorical principles (e.g., THE BODY AS CONTAINER FOR THE EMOTIONS), and metonymic principles (e.g., PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION) that are shared by both languages may be argued to be motivated by universal human experience. On the other hand, the differences found here in terms of source domains as well as the specific elaborations/construals of shared conceptualisations may be interpreted as suggesting two possible things: (1) that the emotions are conceptualised differently in the two languages (2) that different aspects of the same generic-level conceptualisations of the emotions are highlighted/hidden in each language.

Proponents of the cultural embodied prototype view explain this phenomenon by proposing two kinds of embodiment: (i) physiological embodiment and (ii) culturally specific

embodiment, also known as non-physiological embodiment. For instance, THE BODY AS A CONTAINER FOR ANGER metaphor which was shared by the two languages may be said to exemplify physiological embodiment while the specific body parts mentioned in the elaborations of this highly schematic conceptualisation, e.g., *blood, eyes, guts* (in English) and *chest, heart, stomach* (in Akan) exemplify culturally specific embodiment. Maalej (2004:173) has argued that in culturally specific embodiment, a particular emotion establishes a conventional cultural correlation between a body part and a certain conceptualisation of an emotion, e.g., the conceptualisation of anger as redness of skin around the neck and face area in English, so that there is a fusion of culture and physiology.

While anger is conceptualised in terms of redness of skin around the neck and face area in English, Hungarian, Chinese etc., such metonymic/metaphorical conceptualisations of anger in terms of changes in skin colour, are not supported by the Akan data or Wolof data (Munro 1991). Going by Maalej's (2004) claims, therefore, we may conclude that the English specific realisation of the general metonymic conceptualisation THE EFFECTS OF AN EMOTION STAND FOR THE EMOTION in terms of REDNESS OF SKIN COLOUR is a matter of cultural salience. For instance, it is easier to see the change of skin colour on light-skinned bodies than it is (if possible at all) to see it on dark-skinned bodies.

Typically, native Akan speakers as well as native Wolof speakers have dark-skinned bodies. However, typical native speakers of English, Hungarian, Chinese etc. have light-skinned bodies. Since it is easier to see any changes in skin colour on lighter-skinned bodies than on darker-skinned bodies, the physiological effects of an emotion (e.g., anger) based on changes in skin colour are likely to be culturally more salient (and therefore get encoded in their metaphorical/metonymic conceptualisations) in light-skinned bodied cultures, e.g., English, and Chinese. However, since such physiological effects appear not to be culturally salient in dark-skinned bodied cultures, any metaphorical/metonymic conceptualisations relating to changes in skin colour are not highlighted and therefore do not get encoded in their metaphorical/metonymic conceptualisations.

This paper has explored the role culture plays in the metaphorical/metonymic conceptualisations of ANGER in two languages/cultures, Akan and English explaining the similarities and differences in these conceptualisations (both in terms of source domains and the language-specific construals and elaborations) in terms of the general assumptions of the cultural embodied prototype theory. The paper concludes that embodied cognition may be grounded as much in socio-cultural salience as in universal human experience. Thus, this is a viable area of research not only for Akan scholars but also for cognitive anthropological researchers. For instance, this paper has focused on one emotion concept only so it would be interesting to find out the kind of results a focus on other concepts would yield.

ATTENTIONAL PROFILES OF PARENTHETICAL CONSTRUCTIONS: SOME THOUGHTS ON A COGNITIVE-SEMANTIC ANALYSIS OF WRITTEN LANGUAGE*

Martina Lampert

Johannes Gutenberg-University Mainz (JGU), Germany

ABSTRACT

This paper's focus are verbal sequences which, in the written modality of alphabetical orthographic systems, are marked off from their linguistic environment by a conventionalized set of figural elements out of a non-alphanumeric representational system (typically, parentheses, dashes, or commas).

As these parenthetical constructions are (even traditionally) associated with some notion of attention, Talmy's (forthcoming) factor model of linguistic attention, informed by a sophisticated theory of language-specific attentional parameters, offers a coherent theoretical and powerful analytical framework that is both sufficiently independent and general to allow for a systematic and encompassive investigation of these constructions' attentional specifics.

Proceeding from Talmy's analysis of parenthetical delivery in the spoken modality, some initial suggestions will be submitted of how to adapt his insights into attention and parentheticality to the particular conditions and specific demands of the written language: Two fundamental attentional mechanisms from a category of causal factors affecting linguistic entities in the context, Backgrounding the target and Targeting a concomitant of a referent, are scrutinized for a systematic analysis of major constructional variants of parenthetical constructions.

Applying this novel and promising approach, it proves sensible to delineate an attentional profile of (the) parenthetical construction(s) based on a(nother) pivotal factor, The generalized form-semantics association.

* This article is an expanded version of a lecture given at the 9th China International Forum of Cognitive Linguistics (CIFCL 9), Beijing, on July 7, 2011. My thanks go to Thomas Fuyin Li for inviting me to the Forum.

Keywords: Leonard Talmy, Talmy's attention system in language, parenthetical construction(s), written modality

1. THE BASIC PERSPECTIVE: ATTENTION AND PARENTHETICITY

For several years now, the major focus of my linguistic study has been attention in language as it is captured in Len Talmy's emerging framework. And one particular phenomenon that has, even traditionally, been associated with the concept of attention, though at most vaguely and intuitively, are verbal sequences which, in the written modality of alphabetical orthographic systems, are marked off as parenthetical from their linguistic environment¹ by a conventionalized set of figural elements, originally pertaining to a non-alphanumeric representational system.

Such parenthetical constructions², immediately susceptible to a systematic and genuine cognitive semantic analysis, will be the target of my paper; the illustration to follow may convey some idea of both their structural variability and complexity:

(1) The rejection of the idea of an academy was to be important in the subsequent development of the language. From that time forward it was clear that the state was not to play a major role in regulating and reforming the language, whether in England or the other nations of the language community—a characteristic that makes English different from many other languages. (In languages like French and German, for example, spelling reforms can be introduced by official commissions charged with drawing up rules which are then adopted in all textbooks and official publications, a procedure that would be unthinkable in any of the nations of the English-speaking world.)

The second sentence in (1) introduces two such parenthetical constructions: The first (underlined) sequence is marked off by a comma, and the second (indicated by the dotted line) by a dash. The third sentence (in parentheses) exemplifies the putative prototype in terms of formal mark-up, and it contains yet another (underlined) sequence separated off by a comma, representing a specific constructional type that regularly includes one from a set of lexicalized expressions, here *for example* (indicated by the wavy line).

In general, parenthetical constructions prove an under-researched phenomenon in (recent) linguistics: Since M. Lampert (1992) there has neither been any systematic, let alone in-depth, examination in the written modality, nor has there ever been any serious analysis of their

¹ I follow Talmy's (forthcoming:2) terminological suggestion to limit *environment* to "the overtly manifested discourse and physical spatiotemporal surround, while *context* can also include more implicit or abstract phenomena such as the overall subject matter of a discourse, the models of the discourse content cumulatively constructed by the participants in the course of their interchange, the participants' background knowledge, and their mutual knowledge of each other".

² For the term parenthetical construction, see M. Lampert (1992:16). Unless otherwise indicated, all examples in this study are from Nunberg's (1999) "Introductory Essay to the Norton Anthology of English Literature, Seventh Edition", which discusses the diversity and unity of the English language through its history and which may be considered an accessible piece of academic prose, conforming to its expected register characteristics and exhibiting distinctive genre conventions. I chose this text on purpose since its author is arguably a professional writer of academic prose and an expert in English punctuation (cf. Nunberg 1990, co-author of "Punctuation" in Huddleston and Pullum 2002), hence the attestations can be seen as undisputable and representative exemplars of English academic writing.

attentional implications—and this is true of both the set of figural elements used to mark off sequences of a text as parenthetical³ and of the parenthesized sequences themselves. This deplorable state of the art may, in part, have been due to the lack of an adequate analytical tool that is sufficiently explicit to capture (all) the relevant characteristics to yield attention as a central notion for parentheticality as a cognitive concept and for parenthetical constructions as a linguistic category. The present study, actually taking up some insights from my 1992 investigation, aims to partially compensate for these shortcomings; however, all it can do is outline the very beginning of a new research project, sketching the fundamental significance of attention for both the concept and the linguistic manifestation of parentheticality. The reason why I am now in a position to do so is Leonard Talmy's work in progress on *The Attention System in Language*⁴, which presents a sophisticated factor model situated within a coherent theoretical⁵ framework of (linguistic) attention that proves to be both sufficiently independent and general to allow for a fine-grained analysis of parenthetical constructions (apparently also) in the written modality.

Proceeding from Talmy's own (2000, 2007a, forthcoming) attentional analysis of parenthetical delivery, I will, as a complement, offer some initial suggestions of how to apply, or adapt, his insights into attention and parentheticality in the spoken modality to the particular conditions and specific demands of the written language. In this vein, taking the spoken and written modalities as "different and equal manifestations of language" (Crystal 2010:185), I will discuss and delineate essential prerequisites for an attentional profile (cf. M. Lampert 2009) of (the) parenthetical construction(s as a general constructional pattern)⁶ which will address some notorious queries reoccurring in the literature, concomitantly demonstrating that parenthetical constructions, in general, are especially susceptible to an application of Talmy's attention framework. Since my paper is supposed to be an initial attempt toward such an analysis, there will be, needless to state, more questions than answers—not least due to the intricacies of the construction itself in both its wide range of functions and forms, as the following exposition will hardly fail to convey.

2. THE 'RECEIVED VIEW': INCIDENTAL INFORMATION AND PERIPHERAL STRUCTURES

Interestingly, among the fundamental problems that keep re-emerging even in the few accounts of structures that would qualify as parenthetical constructions in the sense adopted here are terms that, in one way or the other, in fact invoke attention as a basic explanatory construct. To just very selectively mention a few references alluding to this very concept: The

³ Some treatment, however, can be found in the context of punctuation studies, e.g., Gallmann (1985), Nunberg (1990), Bredel (2008).

⁴ I would like to thank Len Talmy for the privilege of having access to a very substantial current draft version of this forthcoming book (by MIT Press); page numbers in references to this draft are mine.

⁵ This is in contrast to Nunberg's (1990:25) study, which in its basic arguments and major insights appears to be essentially compatible with my view, but explicitly disregards "the question of which framework is most appropriate for text-grammatical description" and instead attempts "to present [the] observations, where possible, in a theory-neutral way". (I express my serious doubts whether such theory-neutrality is possible on principle; I will not, however, be concerned with this meta-theoretical issue.)

⁶ It remains to be settled whether a generalized construction or a set of variant constructional types would be the theoretically preferable solution.

first comprehensive treatment of the ‘parenthesis’ in modern linguistics may be Eduard Schwyzer’s (1939) seminal study, which associates parenthetical constructions with ‘an aside meaning’ („Zwischengedanke“ or „Nebengedanke“, 32-33) that is considered ‘alien’ to the primary layer of information and conceived of as ‘disrupting’ both the syntactic structure⁷ and the line of argumentation of their environment; hence, in rhetoric or stylistics (and in the notorious usage guides, but also in some grammars), parenthetical constructions are usually considered as either undesirable or as negatively connoted digressions, testifying to authors’ lack of clarity in organizing their texts.

Along the same lines, major current reference grammars of English locate the content(s) of parenthetical constructions “in the shade as background”, as “additional” and “related”, providing “supplementary information” which is “not part of the main message” (Biber et al. 1999:137). And, almost as a necessary consequence, the terminology used in the grammars to describe parenthetical structures invokes the concept of (less or lesser) attention: Parenthetical constructions qualify as peripheral elements of clause grammar (Biber et al. 1999); or when specified in terms of the syntactic patterns they allow, syntactic categories like comment and complement clauses along with appositive or non-restrictive (relative) clauses are the relevant surface structures regularly associated. In more idiosyncratic, or at the same time (allegedly) more general terminology, parenthetical constructions emerge as non-dependent, disintegrated supplements (see Huddleston and Pullum 2002:1350)—all of which imply the connotation of minor (structural) relevance.

In contrast to their pervasiveness and versatility in the more formal registers of written language⁸, the absence of any in-depth study⁹ testifies to the general inattention to parenthetical constructions as a ‘self-contained’ object of research in its own right—quite iconic perhaps to their presupposed communicative function. If parenthetical constructions have become the topic of (recent) research at all, it has been with exclusive reference to the spoken modality (cf., e.g., Dehé and Kavalova 2007). It may be added that both Nunberg (1990:1ff) and Bredel (2008:3ff) attribute this scientific neglect (not only) of parenthetical constructions in written language to the general misconception of a tacitly presupposed wide-ranging (if not complete) equivalence of the two modalities, following from the deep-rooted structuralist bias toward (or ideology of) the spoken language as a primary and ‘true’ medium of communication.

⁷ Note that it is syntax (in the reference grammars but also in most current linguistic research) that has turned out to become and still remains the exclusive reference domain of parenthetical constructions.

⁸ Both frequencies of occurrence and structural complexity of parenthetical constructions seem to increase toward the written end of the spoken-written continuum, i.e., those registers that are at a considerable distance to casual and spontaneous conversation. Among fundamentally relevant issues that I will, for reasons of space, have nothing to say about are those related to the register and genre perspective (in the sense of, e.g., Biber 1988 and Biber and Conrad 2009), which keep re-emerging throughout my exposition and which would most urgently need a dedicated study of their own.

⁹ I explicitly endorse Nunberg’s (1990:104) assessment that “the parenthetical, which while far less well studied than the quotation is actually more central to an understanding of the relation of a written text to its context of interpretation”.

3. THE CONCEPTUAL BASIS: GENERAL ATTENTION AND THE ATTENTION SYSTEM IN LANGUAGE

It amounts to a truism to state that attention phenomena are no less than ubiquitous in human cognition—indeed, attention appears to be one if not *the* crucial cognitive principle(s) rooted in the very functioning and evolution (not only) of humankind¹⁰: It has unequivocally been described as one major vital processing mechanism that directly follows from an organism's survival instinct to select relevant objects from the wealth of information present in the organism's environment—be it concrete objects or information for the immediate need to survive, like finding food or warning signals in the animal kingdom, or more artificial objects and information that safeguard survival in a culturally sophisticated and highly literate community in human societies. In fact, the very first sentence from the preface of a recent collection of over 700 pages and over 100 articles summarizing the state-of-the-art in the neurobiology of attention addresses many of the major issues and problems that attention research is coping with to this day: “Key to the survival of many biological organisms is their ability to selectively focus neural processing resources onto the most relevant subsets of all available sensory inputs.” (Itti et al. 2005:xxi)

And it is the general cognitive capacity humans are endowed with, in any of the cognitive (sub-)systems including language, to selectively and differentially distribute their attention over the world-to-be-conceptualized. That is, language itself has evolved as an important mechanism, “directing the interlocutor to make particular focal adjustments ... as he or she creates a mental representation of the meaning packaged in the incoming message” (Taube-Schiff and Segalowitz 2005:508). Given both the ubiquity and the relevance of attention for human survival, there is a highly deplorable state of research on attention and/in language, quite in direct contrast to the plethora of studies, e.g., in cognitive science. And even if Talmy (forthcoming:3) in all modesty concedes that “[m]uch previous linguistic work has involved the issue of attention or salience”, these attempts have yielded indeed only a very fragmentary view of how attention and language link up, not least because research has been pursued in terms of such simplistic and parsimonious dichotomies as topic and focus, given and new, theme and rheme, foregrounding and backgrounding. In view of the limited scope of such approaches (with attention management being mostly confined to focus shifting, referent choice, and assignment of syntactic functions), it makes perfect sense to claim that it is Talmy's (forthcoming:3) recent research which, in his own words,

“may be the first with the aim of developing a systematic framework within which to place all such prior findings—together with a number of new findings—about linguistic attention. In fact, this study is perhaps the first to recognize that the linguistic phenomena across this whole range do all pertain to the same single cognitive system of attention.”

It has been a central commitment of Len Talmy's research agenda, with its decisively cognitive focus and explicit interdisciplinary orientation, to acknowledge the systematic interaction of general attention and language. This link-up of general attention and language becomes feasible in an extant system of language-specific attention which is part of the Overlapping Systems Model of Cognitive Organization (Talmy 1995ff), exhibiting a

¹⁰ The following sketch has been adapted from M. Lampert (2009:4ff).

significant overlap, but no coextension, of language with other cognitive systems (e.g., vision), on the one hand, and system-specific particularities of the language system, on the other.

Perhaps the greatest asset of Talmy's approach to attention is its conceiving the selective and differential distribution of attention over the components of a referent scene as being grounded in a system of "particular linguistic mechanisms" (e.g., Talmy 2007a:264) that inherits its characteristics from general cognition—hence pays respect for all kinds of attentional variability. And this model accounts, in its current 'revised' version, for this diversity by proposing a relatively closed universally available inventory of attention factors which may be individually combined and successively integrated into a comprehensive and highly flexible system of attentional patterns or schemas. In analogy to Talmy's seminal work on the representation of spatial structure in spoken and signed language, such attentional schemas can be considered a "pre-packaged" (Talmy 2003:169) bundling together of attention factors in a particular arrangement. It may ultimately be reminiscent of, and, indeed, find its conceptual analogy in the 'binding together' into 'assemblies', perhaps by synchronized neuronal firing, of distributed neural activity, making his framework compatible with one prominent view on the functioning of attention in the brain; see M. Lampert (2009).

In its current adaptation, 'Linguistic Attention' details a conceptual system of individual attention-specifying devices in language directly relating to cognitive processing, to the effect that any (semantic) component or (surface) constituent of a given linguistic representation is increased or decreased in its (relative) attentional weight. Any such mechanism, "formulated as a contrast between greater and lesser attention" (Talmy forthcoming:1), inherits its characteristic dichotomy from the central nervous system's basic biology, just to impose on this fundamental neurochemical all-or-none mechanism the attentional system's gradient character. To illustrate: Language as a cognitive system, on a par with other cognitive systems like visual perception, the motor system, or culture, is likewise affected by attention as a fundamental cognitive principle, and its effects can be prominently identified as system-specific reflexes of general attention. In light of one such basic attentional principle, e.g., "greater magnitude along a cognitive parameter tends to attract attention to the entity manifesting it", this effect translates into language, for instance, as "stronger stress on a linguistic constituent", while in visual perception it corresponds to, say, "a large size or bright color of a viewed object" (Talmy 2007a:266). That is, the operational system of attention and the substantive system of language converge to generate 'Linguistic Attention', giving rise to a specialized and differentiated inventory of attentionally specified manifestations on all levels of language structure.

In its most recent version more than fifty individual linguistic attention mechanisms assign "different degrees of salience to the parts of an expression or of its reference or of the context" (Talmy 2007a:264), specifically direct hearers' attention and, given the cognitive endowment of humans, would, in the case of written language, also distinctively guide readers in processing parenthesized sequences' structure and contents. The underlying general principle becomes manifest in causal factors that each yields a specific attentional effect (and this effect is different for hearers and speakers—hence, there are hearer- and speaker causal factors). In the following I briefly survey the Attention System's components and internal structure, with individual attentional mechanisms or Areas grouping in (hierarchically organized) Subdomains and Domains:

Domain A is concerned with attentional properties of the morpheme, including Subdomain Aa, Symbolic properties of the morpheme, divided again into Area Aa1, The shape-concept association of a simplex morpheme, and Area Aa2, The generalized form-semantics association of a construction. This is the critical factor for the constructional pattern at issue, which I will briefly comment on below.

Domain B, Attentional properties of a morpheme combination, again differentiated into Subdomains and Areas, I will, for the time being, completely disregard; it would, however, have to be included in an in-depth analysis of parenthetical constructions' combinatorial properties¹¹.

Of immediate relevance for this paper, Domain C, Attentional effects of one entity on another, covers contextual factors in a very broad sense and accounts for intricate context-based effects in a remarkable degree of granularity. For the present study of parenthetical constructions, I will especially have recourse to two Areas of Subdomain Ca, Dedicated causal triggers, that capture attentional effects of one entity on another, namely, Area Ca2, Targeting a referent other than as focus, as well as Area Ca4, Targeting a concomitant of a referent. In contrast to Domains A and B, where the causal factors involve "entities acting in concert or acting on each other mutually, or even acting on themselves reflexively" (Talmy forthcoming:1), the attentional mechanisms of Domain C specify asymmetric effects of one entity on another, that is, they affect entities in the (linguistic) context outside themselves. One of its specific characteristics, particularly relevant in the present context of analysis, "shared-environment triggering", involves "two separate entities ... co-present in a discourse", with the first entity, the (effecting) trigger(ing device), "affecting attention on the other", the selected target (Talmy forthcoming:1).

To achieve this (asymmetric) effect, "the causal trigger must engage some device to select out the relevant second entity from all the entities co-present in the environment and designate it as the causal target"; more precisely, the causal factors operative in this Domain yield "two distinguishable attentional effects": First, a target-yielding phase raises the activation level, hence increases the salience, of the selected entity—an immediate effect of the entity's "designation as the relevant entity out of the entities co-present in the environment" (Talmy forthcoming:2). In a second phase, the target-weighting phase, a further attentional effect is operative that may range from "minimal to substantial": Attention on a target's content "can be increased, decreased, or kept down—that is, the content can be activated, attenuated, or inhibited", which in turn gives rise to the distinctive "dual character of the selectional target and its differential attentional treatment" (Talmy forthcoming:3), characteristic of the present Subdomain. First, the target is highlighted as the selected-out entity, and, in its target-weighting phase, a second attentional effect results in a twofold attenuation in the target's salience, instructing the addressee to consider its referential content as incidental.

Next, Subdomain Ca includes two attentional mechanisms which appear to be of major significance for parenthetical phenomena: Of these, Subarea Ca2(b), Backgrounding the target, identifies a prosodic device as trigger and the prosodically differentially realized

¹¹ Nunberg (1990:36) observes that the parenthetical is "an element of both the text-grammar and the lexical grammar of the written language". Bredel (2008:37f) also claims the discourse level as determinant for parenthetical sequences marked off by parentheses or dashes but not for those separated by commas. Whether it may be reasonable to differentiate between the respective effector domains, syntax versus text, or whether to assume a transitive and hierarchical succession of effects would be more appropriate remains an open issue.

sequence as target, which together capture the attentional effect(s) of parentheticality in the spoken modality, viz. parenthetical delivery. And for the specific constructional type mentioned above that regularly includes one from a set of lexicalized expressions such as *for example*, I will recruit Ca4, Targeting a concomitant of a referent, as a relevant causal factor (see section 5.5). Figure 1 (below) has been drawn up to provide a survey of and contextualize the factors referred to in the analysis to follow.

In addition, to account for some systematic correspondence between the admissible (or possible) figural element (parentheses, dashes, or commas) and its differential (textual) distribution, Talmy's (forthcoming: 6) concept of (types of) constructional slotting suggests itself as explanatory construct:

As a "single more general [triggering] device" constructional slotting details for the generalized form of a construction a structurally designated slot, specifying three distinct devices operative in a given linguistic environment, namely, relative positioning, overlay, and syntactic inclusion, that is, "a trigger entity can select out a target entity within the same environment by occurring beside it, over it, or around it" (Talmy forthcoming:2). Each structural variant of the parenthetical construction will turn out to associate one such device, which may well also (at least in part) account for modality-specific preferences. In the case of sentence-initial and -final parenthetical constructions, relative positioning, i.e., the 'beside' type, is seen to operate; parenthetical delivery, the 'over' type, "can be interpreted as one part of a construction that also contains the constituent it overlays" (Talmy forthcoming:6f), while syntactic inclusion, i.e., the 'around' type, characterizes the sentence-medial (proto-)type of parenthetical constructions. The written modality, then, allows for two out of the three slotting devices and specifies the generalized form of the parenthetical construction—either syntactic inclusion or relative positioning as may be observed in (1), which exemplifies both types of slotting: the sentence in parentheses in the third sentence, and two sequences marked off by a comma and a dash in the second sentence respectively. Overlay, in contrast, is reserved for the spoken modality only. These constraints in slotting devices testify to the strict(er) principle of linearity in written language (cf. Bredel 2008:9. 30f).

4. THE SPOKEN MODALITY: PARENTHETICAL DELIVERY

Overlay, then, as a slotting device is indicative of the attentional profile of parenthetical constructions in the spoken modality: Factor Ca2(b), Backgrounding the target, specifies an attentional mechanism that operates over a linguistic target and gives rise to its characteristic dual nature (as mentioned above). "The parenthetical delivery of an expression seems in general to reduce a hearer's attention on the expression's meaning", yielding an assumed effect that consists "mainly of a reduction in loudness and a lowering of pitch over the expression, while it maintains the internal loudness and pitch relationships—and specifically the stress relationships—among the constituents of the expression"; as a result, "expression-spanning loudness reduction and pitch lowering are together ... able to trigger attentional decrease in a target—in particular, to attenuate the expression's reference" like in the following parenthesized clause, "which, if pronounced as just described, seems to encourage a hearer to treat its content as merely incidental information, readily disregarded" (Talmy forthcoming:48):

Figure 1. The Domains and Subdomains, Areas as well as Subareas of Leonard Talmy's (forthcoming), *The Attention System in Language*, relevant for the analysis of parenthetical constructions; the shaded boxes indicate the factors that are specifically addressed in this paper.

(2) *My cousin Sue (who happened to be visiting at the time) wanted to go to the museum.*

Talmy (forthcoming:49) states that the “attenuative effect of reduced loudness over an expression derives readily from the attentional principle of quantity”, involving a general cognitive principle: “the smaller the magnitude of some perceptual dimension of a form—here, its loudness—the less salient its referent”; in contrast, the second attenuating effect, lowered pitch, “is not a reduction in any physical parameter—only a specifically directed overall shift in frequency or in wavelength. No general attentional principle that might account for its attenuational effect is obvious.” (Note that this effect—though attenuational—basically rests on a difference principle and might as such be similar to a potential but non-used device in the written modality, e.g., italics to mark off the parenthesized sequence, see 5.4 below.)

In the spoken modality, then, this attenuating type of dedicated triggering device is seen to uniformly lower the salience of both the target form and its referent; i.e., the specific prosodic delivery causes a reduction in hearer attention on the expression’s meaning by reduced loudness and lowered pitch over the parenthetical target. And this reduction in the physical parameters, in turn, decreases attention on the parenthetical target and its referent—the attentional effect, as predicted by the general causal factor. Now, what happens in the written modality?

5. THE WRITTEN MODALITY: PARENTHETICAL CONSTRUCTIONS

In the following, I will probe into major differences as well as correspondences in the ‘attentional behavior’ between spoken and written parenthetical constructions, either allowing for the attentional profiles in the two modalities to overlap to a certain (yet to be specified) degree, or for the language modalities to invoke separate subdomains of attentional mechanisms, which will follow from (categorically) different production and reception possibilities and constraints¹.

To begin with, like in the spoken modality, an author- and reader-causal attentional process of target selection would have to be distinguished that is implemented by a conventionalized set of figural elements from a non-alphanumeric representational system², which designates a sequence marked off by them as the relevant entity, the target; as a consequence, this selected-out parenthesized sequence undergoes activation in its target-yielding phase. The figural elements used in the written modality will most probably generate

¹ Physical and physiological constraints prove to be the major determinants of the language modalities and are of fundamental relevance for any larger-scale investigation; see, e.g., Nunberg (1990: 3f.7.14f); Biber (1988), Crystal (2010), and Talmy (2007b) offer more specific accounts. I cannot, however, go into any details here, but just in passing refer to one fundamental aspect in Talmy’s (2007b) intriguing evolutionary analysis of production and reception circumstances and their ensuing modality-related aspects such as change in the representational format due to the physical constraints of the medium, which separates the analogous, coextensive, and simultaneous spoken system, allowing for gradient and relative distinctions, from the digital and discrete written system of representation, disallowing gradient and relative distinctions.

² Nunberg (1990:6f) emphasizes the independence of this figural “linguistic subsystem” as relatively autonomous and sets it on a par with non-linguistic graphical-representational systems; see also Bredel (2008:10ff). The semiotic interpretation of the figural elements (as indexical, iconic, or rather symbolic elements), however, awaits research; interestingly, Crystal (2010) does not even comment on, let alone specify, the relation of punctuation and graphemes.

an analogous foregrounding effect assumed for the corresponding prosodic device in the spoken modality: an increase in attention on the target following from the fundamental cognitive principle of (perceptual) difference. At the same time, the non-alphanumeric elements, marking up parentheticality in the written modality, qualify as devices that attract attention on themselves, as predicted by the general causal factor operative in Subdomain Ca (see section 3)—exactly how and to what extent they will do so calls for both an in-depth analytical study (taking into account also the historical process of their conventionalization) and an empirical examination (including neuroscientific methodology). As I will argue further, there is, however, a categorical difference both in the type of triggering device and in its effect; to support this claim, I will, first, sketch what it, most probably, means from the perspective of a reader to encounter a sequence in a text exhibiting the perceptual features mentioned. To this end, some terminological suggestions and exemplification of major structural types are in order.

5.1. The Constituents: Parenthesizers, Specifiers, and Parenthesized Sequences

Parenthetical constructions consist of the following structural constituents, with two of them (the figural elements and the parenthesized sequences) being obligatory, and one optional (provisionally called specifiers; see 5.5). Typically, a pair of non-alphanumeric figural elements, a selection from the inventory of conventionalized punctuation marks³, serves as triggering devices to select out the parenthetical target, which I suggest to call parenthesizers. They conform to Talmy's definition of dedicated triggers (see above) and fall into three subcategories, subject to specific (systemic and textual) constraints: parentheses, dashes, commas, and to illustrate them, I will present one example each (from the 'corpus'). Parentheses, for instance, obligatorily occur in pairs:

(3) *Yet for all these changes, there is a continuity here, too, in the way that change is (sometimes heatedly) debated and (sometimes grudgingly) accommodated.*

Dashes in pairs are also mandatory in medial sentence positions (note the specifier *that* is in this example; see below 5.5 for some details):

(4) *It [English] has between 400 and 450 million native speakers, perhaps 300 million more who speak it as a second language—well enough, that is, to use it in their daily lives—and something between 500 and 750 million who speak it as a foreign language with various degrees of fluency.*

And commas are likewise required in pairs in sentence-medial positions⁴:

³ Cf. Nunberg's (1990:36) "delimiters", left and right, as opposed to "separators", typically occurring singly.

⁴ I will have nothing to say about the long-standing notorious issue of which candidate syntactic structural types marked off by commas are to be included as representatives of parenthetical constructions.

(5) *Its grammar was simplified, continuing a process already under way before the Conquest, and its vocabulary was enriched by thousands of French loan words.*

Of the three slotting options introduced in section 3, parentheses are exclusively of the syntactic inclusion ('around') type, while dashes as well as commas are positionally variable (and polyfunctional), and, following from this characteristic, generally conceived as more ambiguous in their capacity to indicate parentheticality⁵. The relative positioning ('beside') type comes in two forms, here illustrated by the sentence-initial case with a dash or a comma:

(6) *Belittle, influential, reliable, comeback, lengthy, turn down, make good—all of these [words] were originally American creations, and give an indication of how independently the language was developing in the New World.*

(7) *Seen from that exclusively linguistic point of view, there would be nothing to distinguish the evolution of Anglo-Saxon into the varieties of modern English from the evolution of Latin into modern French, Italian, and so forth—we would not be able to tell, that is, why English continued to be considered a single language while the Romance languages did not.*

As can be seen in (7), which also contains a second parenthetical construction of the 'specified' type (*that is*) in sentence-final position, dashes (dotted lines) and commas (underlined) may also occur singly and in combination in sentence-final position as (8) and (9) demonstrate.

(8) *We also have to follow the play of centrifugal and centripetal forces that kept the language always more or less a unity—the continual process of creation of new dialects and varieties, the countervailing rise of new standards and of mechanisms aimed at maintaining the linguistic center of gravity.*

(9) *From that time forward it was clear that the state was not to play a major role in regulating and reforming the language, whether in England or the other nations of the language community—a characteristic that makes English different from many other languages.*

(8) and (9), examples of syntactic positioning, combine a comma and a dash, demonstrating, first, the parenthetical constructions' nesting potential and structural complexity (in the formal written registers); second, they illustrate the intricacy of the combinatorial constraints on the two triggers that appear to follow some (attention-related) functionality. For reasons of space, I will not comment on the admissible variants, but see for some suggestions Gallmann (1985:34ff), Nunberg's (1990) absorption rules, and Bredel (2008:34-43).

⁵ This is an attention-related feature, since it seems cognitively plausible to liken 'polysemy' in functional parenthesizers and polysemy in morphemes, which is the focus of Talmy's Subdomain Ae, and which is regularly associated with an attenuative effect on the morpheme's referent. As an immediate consequence, these variants prove problematic in terms of inclusion in or exclusion from a structural category of parenthetical constructions, see previous note.

Yet, there seems to be some room for individual (stylistic?) choice as when in (10) dashes would be a possible alternative for the paired commas and perhaps also for the parentheses (which could, with some change in ‘meaning’, also be replaced with commas, provided the author would not wish to use a figural type twice in the sentence). In any case, it would require a thorough empirical study to document and detail such constraints.

(10) *The resulting total of between 1.2 billion and 1.5 billion speakers, or roughly a quarter of the world’s population, gives English more speakers than any other language (though Chinese has more native speakers).*

Example (11) testifies to a notable attentional bias underlying the English convention to systematically and functionally differentiate between relative clauses by means of punctuation, which, in turn, offers a clear motive to include non-restrictive relative clauses in (at least the ‘national’) category of parenthetical constructions; see M. Lampert (1992), and e.g., Gallmann (1985:144f), who argues against reforming the non-functional, formal-syntactic convention in German.

(11) *The language itself continued to change as it moved into what scholars describe as the Early Modern English period, which for convenience sake we can date from the year 1500.*

The two remaining categories of triggering devices, (Arabic) digits for foot-/endnotes, appendices, and hypertexts as well as graphical devices of text layout (e.g., indentation of paragraphs) will not be a topic in the present article. I will, however, briefly comment on a specific type of parenthetical constructions containing specialized lexical items which may constitute a (structural and functional) constructional variant. These “linguistic forms, intrinsically lexicalized to perform the function of designating a particular target through a specific device” (Talmy forthcoming:3), will provisionally be termed specifiers: *for example, that is, by contrast, in particular* etc. (for whose analysis I will have recourse to another causal factor from Talmy’s language-specific system, see 5.5 below).

And, finally, there are the (obligatory) parenthetical targets marked off by the parenthesizers (and optionally accompanied by the lexical items referred to as specifiers; see 5.4 for some of their attentional specifics). To briefly illustrate the structural variability and complexity of the parenthesized sequences, which may range from the submorpheme level to whole text fragments, (12) through (14)⁶ exemplify the minimal end, a parenthesized grapheme and (a sequence of) punctuation marks, exclamation points or questions marks:

(12) *W(h)ither English?*

(13) *He took pianists, guitarists and harpists in stride, but expressed shock at “13 young lady violinists (!), 1 young lady violist (!!), 4 violoncellists (!!!) and 1 young lady contrabassist (!!!!).*

(14) *While ego orientation did not emerge as a significant predictor of likelihood to aggress in any of the three groups, significant correlations were found between ego*

⁶ Examples (13) and (14) are retrieved from the *Corpus of Contemporary American English*. <http://www.american corpus.org>

orientation and likelihood to aggress for boys, $r(???) = .20, p < .005$, and girls in the all-girls league, $r(???) = .40, p < .005$.

Note that for the last two cases it would be hard to maintain the idea that the content of a parenthetical construction by necessity be attentionally attenuated; see for some details section 5.5 below.

And, additional to the above cases of ‘intermediate’ structural complexity, (15) illustrates an example where the (underlined) parenthesized sequence consists of two full sentences; it is the most complex structure containing parenthesizers (of the first subcategory) found in the ‘corpus’.

(15) *And there is a large number of common words for talking about the language itself, for example slang, usage, jargon, succinct, and literate. (It is striking how many of these words are particular to English. No other language has an exact synonym for slang, for example, or a single word that covers the territory that literate covers in English, from “able to read and write” to “knowledgeable or educated”).*

To just add one brief note on the textual contingency of the parenthetical construction, which would readily require an extended study of its own based on a detailed register, style, and genre analysis in the first place (see footnote 8): After the ‘closing’ parenthesis, the text continues with a new paragraph—which may well support the argument that the genuine linguistic ‘level’ at which the parenthetical construction should exclusively and can consistently be analyzed is the text (see footnote 11). Due to space limits, I will refrain from illustrating parenthesized targets of the paragraph type.

5.2. The Reader’s Perspective: Some Tentative Remarks

As a first step, it may be sensible to survey some perceptual characteristics that will probably catch readers’ attention when they encounter a parenthetical construction in a given written linguistic environment.⁷ For reasons of both simplicity and space as well as for want of serious studies, I will restrict my preliminary illustration to parentheses, the presumed prototypical case of parenthesizers, like in (3) reprinted from above:

(3) *Yet for all these changes, there is a continuity here, too, in the way that change is (sometimes heatedly) debated and (sometimes grudgingly) accommodated.*

Following the linearity constraints of the reading process, a reader of (3) will, after two graphemes in succession, the second occurrence of *is*, and an obligatory blank space, encounter one figural element from the non-alphanumeric set characterized in section 5.1 above, in this case the left-hand parenthesis. This ‘opening’ parenthesis is immediately followed by a succession of graphemes, which, interrupted by another blank space, separating off two lexical items in their specific linear sequence, constitute the appropriate word forms required by the constructional slotting, the adverbial phrase *sometimes heatedly*.

⁷ In this description, I do not imply any claim whatsoever about the actual on-line processing.

Directly attached to the second word form is another such figural element, the complementary right-hand ‘closing’ parenthesis, signaling the end of the parenthetical construction, which is followed by another blank space and another sequence of uninterrupted graphemes, here the main verb *debated* (which represents the predicate of the first clause and is often referred to as the host, or anchor, of the parenthetical construction, cf. Huddleston and Pullum 2002:1351). (Again, it is an empirical issue whether, plausibly so in the present case, readers will have both parentheses in their visual focus, processing them ‘simultaneously’ as a pair; aspects like readers’ familiarity with the pattern and/or the content of the text etc. will also play a role.)

To analyze the effect of the parentheses on the reader in general perceptual terms would mean to specify the figural elements as salience phenomena that relate to an inherent physical quality of this stimulus which is subject to bottom-up, data-driven visual processing. Typically, stimuli of a different shape than their environment generate a fundamental perceptual pop-out effect, which is a basic attentional ‘behavior’ similar to the orienting reflex well-known in pattern recognition and visual feature integration research since the seminal study by Treisman and Gelade (1980). The attention phenomenon encountered here can, in a functional perspective, be epitomized as novelty effect (that is, novel items tend to be given priority of processing over familiarized items; cf. M. Lampert 2009:123). The parentheses, then, both left and right, first attract attention to themselves by virtue of their difference in figural shape as against their shared linguistic environment (all of which consists of elements from the graphemic inventory of alphabetical script); and the differential shape is responsible for the parentheses to pop out, and, thus, attract attention to themselves. What exactly this means for on-line processing essentially proves an empirical neuroscientific question: whether readers engage in different processing activities and, if so, what the actual mechanisms are.

5.3. The Triggering Device: Toward an Attentional Characterization of Parenthesizers

In light of this provisional sketch, it is to be expected that the perceptual difference accomplished by the parenthesizers will trigger has an effect on the reader that is accounted for by the causal attention factors introduced above. These predict that the pair of figural elements will set the embraced item(s) off from their linguistic environment and designate them as the selected-out target, which will undergo activation in the target-yielding phase. Whether or not the subsequent target-weighting phase uniformly yields an attenuative effect, as is presumed in the traditional accounts of parentheticality, is very much open to debate. (I will rather submit that the specific attentional effect in the target-weighting phase appears to be crucially dependent on contextual and higher text-level parameters, see 5.5.)

In comparison to the production and reception circumstances of spoken language, which systematically allow for gradient activation and attenuation from “minimal to substantial” (Talmy forthcoming:3)⁸, the written modality does not offer the same relative gradience in a quantitative dimension for its triggering devices (see section 5., footnote 1). The linguistic

⁸ Some experts claim that there may be any indication lacking, even taking (initial) non-indication as the default case for some types, e.g., parentheticals like *I think* (cf. Dehé and Wichmann 2010).

subsystem of parenthesizers in alphabetical languages relies instead on a principle of categorical (figural) difference and, accordingly, has conventionalized only discrete, all-or-none devices—with no perceptually feasible reduction effect that lowering loudness or pitch afford when indicating less salience in some physical parameter. In the written modality, the parenthesizer is either present or absent; that is, there are discrete parentheses, or any other instance from the inventory of markers (dashes, commas, numbered foot-/endnotes), or there are none. Also, these triggers are essentially separative, ‘point-like’ spatial delimiters, unequivocally signaling the beginning and end of a parenthetical construction in the case of the more typical and unequivocal syntactic inclusion type⁹. Again, contrary to their functional equivalent, the overlay of parenthetical delivery in the spoken modality, they are not coextensive with the parenthesized sequence: The first parenthesis in (3) precedes the parenthesized sequence, ‘announcing’, so to speak, that the sequence to follow should be treated differently in some respect (but not necessarily resulting in uniform attenuation; see next section), until the ‘closing’ element is encountered to ‘cancel’ the difference. Like before, it would demand further investigation to find out whether there are differences in activation between the left and right parenthesis (or dashes when they occur in pairs); with reference to the two (competing) general cognitive effects, privilege of primacy and the recency effect (which relates to memory), some differential should however be expected.

In this context, I would like to draw on an analogy which is found in another figural representation system, as when a traffic sign, announcing a speed limit, e.g., is understood to be valid for an explicitly specified or conventionally defined time interval, only to be canceled by a second (different) sign. In semiotic terms, the parenthesizers in the written modality would, as far as their function is concerned, have to be analyzed as indexes, characterized by some diagrammatic iconicity; cf. M. Lampert (1992:74).

Gradience (motivating the diagrammatic iconicity) becomes feasible in the written modality in more than one respect: Here, a secondary gradience effect of attenuation and a possible hierarchy which is imposed on the discrete nature of the parenthesizers would predict a ‘stronger’ attentional impact of parentheses as against, say, commas. As to a provisional suggestion, parentheses (due to their physical characteristics and their exclusiveness in signaling parentheticality) are plausibly assumed to attract more attention to themselves than commas, which are not only ‘inferior’ as functionally underspecified, ambiguous, and competing indicators of parentheticality (cf. Nunberg 1990:83f, non-parenthetical separator vs. parenthetical delimiter) but also for their physical attributes (size, position, and shape, cf. Bredel 2008:24ff). Hence, the target-yielding phase is expected to result in a higher level of activation with parentheses than in the case of commas, eventually giving rise to said prototype effects; and assumptions like these are generally surfacing in the punctuation studies (see, e.g., Bredel 2008:37)—though there is, to my knowledge, no empirical evidence so far that would corroborate such claims.

5.4. The Targets: Attentional Attenuation—A General Effect?

In principle, the written modality would not prohibit attentional gradience with regard to the target. For instance, it might be imaginable that the parenthesized sequence were reduced

⁹ In case the (above) secondary gradience argument is plausible, the effect appears to be less clear for the commas.

in print size, say, 11 pt in a typographical environment of 12 pt, which, though of course being a discrete device, would generate a secondary gradience effect. Or, the use of light fonts in a context of regular fonts (which might then correspond to the reduced loudness over an expression in the parenthetical delivery of the spoken modality) would implement basically the same attentional principle of quantity, i.e., reduction in a physical parameter. But exploiting such attenuating potential of fonts has not been conventionalized as a general ‘visual’ strategy, even if reduced font sizes are common practice in some disciplines of academic writing for quotes exceeding, e.g., three lines, and/or in footnotes. It should perhaps be added that parenthesized targets also do not feature another (non-attenuational) graphical format such as italics that would set them perceptually off from their surrounding to (re-)direct readers’ attention, thus generating a system-specific attentional effect based on a cognitive principle of physical difference like the presumed pop-out effect of the parenthesizers, while retaining the outward appearance of their linguistic environment (see section 4 for an assumed analogy with the parameter of pitch). The only indication of parentheticity is delimiting the sequence.

If, however, Factor Ca2’s impact is generalized to operate in the written modality also, the following query immediately arises: While the first effect, an increase in the parenthesized sequence’s salience qua being the selected-out target, is correctly predicted and achieved by the parenthesizers, how should the attenuative effect that is assumed to hold for the parenthesized sequence’s referent be brought about in the first place? There is no such perceptual parameter that would display the same decrease in target salience as the parenthetical delivery in the spoken modality: The parenthesized sequence is simply not physically different, and so no perceptual effect (in either attentional direction) can reasonably be expected. The assumption of a parenthetical target’s attenuation associated with this constructional pattern can thus only be understood as a convention, an effect of (prescriptive?) formal instruction or cultural practice, which might or might not have been negotiated in the literate community.

Even on first inspection, however, there are numerous counter-examples in the written modality where the referent of the parenthesized sequence cannot plausibly be claimed to just be attenuated—on the contrary, it is rather supposed to be attentionally activated. Examples (12), reprinted for convenience, and (16) may be cases in point:

(12) *W(h)ither English?*

(16) *The (Un-)Emotional Male*

To argue out this point: First, the (conventionalized) formal constraints on the usage of parentheses do not allow for the reverse attentional result—the parentheses necessarily embrace the ‘add-ons’ (<h> and <un->) but not the ‘minimized’ morphemes (<with> and <emotional>); so there is no alternative mark-up available, hence no ‘natural’ (perceptually based) preference, for one or the other reading. Second, a brief analysis of (16) is in order to demonstrate how deliberate writers exploit both the attenuation and the activation effect to create the ambivalence crucial for their intended reading (cf. M. Lampert 2009:345-347). Here is a presumptive paraphrase of *(un)emotional* in its original context, the title of a 2001 article by Mark A. Hurst et al., “The (Un)Emotional Male: Physiological, Verbal, and Written Correlates of Expressiveness”: ‘Though being unemotional may conform to a commonly presupposed stereotype of a male, it is rather the reverse quality ‘emotional’ that is seen to

hold for at least many males'. And the parenthesized bound morpheme (*un-*), in fact, conveys the instruction for the reader to make available the two (contradictory) readings referred to at a time. Hence, it is considered vital, in the present case, to understand the implication that men are *both* emotional (in deviance from the stereotype) *and* unemotional (the 'real' personality trait of a typical male, as the author most probably intends to convey). It is a matter of debate, of course, which of a male personality's facets should in fact be the 'valid' one, and this ambivalence is actually the most probable (intended) message: that men, contrary to their consciously performed or habituated facework, only pretend to be unemotional but are in fact highly emotion-driven beings.

Immediately, the strategic potential of such ambivalence becomes obvious: It is exactly this 'double-speak', or rather: hedging function, of parenthetical constructions that indeed proves a convenient textual strategy to be (consciously) exploited for specific (non-?)communicative purposes. In light of this reasoning, there cannot and should not be any attentional difference in significance between the reading with and without the parenthesized sequence: Neither is there a more attended nor a less attended variant, unless one would exactly presuppose one single¹⁰ cultural model associated with parentheses, since there is in fact no alternative in its formal representation. Again, contextual factors (including readers' mindset and expectation) will play a decisive role in determining the preferred, or 'first', reading.

For the next two examples, reprinted from above, attenuation as an attentional effect of the parenthesized sequence whose referent should readily be disregarded can hardly be a plausible option either. (Note that these are the only attestations of four consecutive punctuation marks in parentheses found in the COCA, but they may illustrate how far even authors of academic articles would go.)

(13) *He took pianists, guitarists and harpists in stride, but expressed shock at "13 young lady violinists (!), 1 young lady violist (!!), 4 violoncellists (!!!) and 1 young lady contrabassist (!!!!)."*

(14) *While ego orientation did not emerge as a significant predictor of likelihood to aggress in any of the three groups, significant correlations were found between ego orientation and likelihood to aggress for boys, $r(????) = .20, p < .005$, and girls in the all-girls league, $r(???) = .40, p < .005$.*

Similar to (12) and (16), the pattern of successively more repetitions of punctuation marks as parenthetical targets is meaningful in this sequence, where a conscious author has chosen to deliberately emphasize their arguments to an iconic, hence 'semantic', effect. These examples of parenthetical constructions, then, if not straightforwardly highlight, but in any case qualify, the intended reading and meta-cognitively indicate a specific type of communicative purpose, that is, they communicate an author's stance, which might result in a polyphonic text structure (see Bredel 2008:148). And whether this will unequivocally result in a decrease in attention remains to be settled, preferably by empirical studies.

¹⁰ For the present examples, then, one would in fact have to postulate more than one function, or structural pattern for that matter.

5.5. The Optional Factor: Dedicated Lexicalized Items, Targeting Concomitants?

As to the structure of the parenthetical construction, there is a variant that, in addition to the non-alphanumeric characters, includes sequences like *for example*, *that is* etc. Here are two examples from the same context that address the very same issue, namely exemplification of lexical changes in American English; disregarding the variation in the parenthesizers for a moment, which is in these two cases probably due to some stylistic (non-functional) consideration since both figural elements could well be used interchangeably, (17) and (18) may qualify as a structural and functional minimal pair:

(17) ... words that had fallen into disuse in England (din, clod, trash, and fall for autumn)

...

(18) Some of these [words] answered to their specific needs and interests—for example, squatter, clearing, foothill, watershed, congressional, sidewalk—but there were thousands of others ...

To account for the difference between these constructional variants, which may not least be an essentially attentional one, it seems plausible to have recourse to Area Ca4, Targeting a concomitant of a referent, a factor that probes into attentional specifics of quotatives. This move in my analysis will rest on acknowledged¹¹—or at least potential systematic (?)—connections between parenthetical constructions and quotations. The link-up is brought about by *for example*, which may be categorized as a triggering device “lexicalized to select out as its target a specific linguistic constituent, together with the constituent’s associated semantics” (Talmy forthcoming:57). I suggest calling these devices specifiers as they verbalize the specific relation assumed to hold between the referent of the parenthesized sequence and the linguistic environment outside.¹² Such dedicated triggers, always optional in addition to the parenthesizers, explicitly instruct the reader to process the parenthesized sequence in a way intended by the author—in (18) as an exemplification; by contrast, (17) does not ‘window’, i.e., overtly express, the presupposed exemplification reading but leaves it to the reader to infer that the words mentioned do not constitute an exhaustive set.

More specifically, as touched upon above, *for example* in (18) appears to match Talmy’s (forthcoming:3) definition of dedicated triggers that are “intrinsically lexicalized to perform the function of designating a particular target through a specific device”, which, however, only selects out a concomitant aspect of the target’s referent. Since this is not familiar territory, I will quote from Talmy’s (forthcoming:57) ongoing research:

“Each dedicated form of this type is lexicalized to select out a particular constituent from the local clause ... and also a particular concomitant of that constituent’s referent. This can be regarded as the target-yielding phase In the target-

¹¹ See, e.g., Nunberg (1990:104) and Bredel (2008:139ff); this analogy is also supported, from a grammaticalization point of view, by the recent development of quotative *be like*, which is motivated by its semantic relation to ‘for example’, see, e.g., Romaine and Lange (1991:253).

¹² In the context of causal factors and their attentional effects, a first issue is whether this instruction is plausibly a part of the target or not; in a purely formal perspective, it is without any doubt a constituent of the sequence embraced in parentheses or dashes—but functionally it would seem more plausible to conceptualize it as yet another type of trigger.

weighting phase, the selected-out concomitant receives increased attention In directing a hearer's attention to aspects of linguistic organization or to aspects of his own cognitive processing, rather than to the direct referring function of a constituent—its default function—such forms establish certain kinds and degrees of meta-linguistic awareness in the hearer pertaining to the constituent or its referent.”

The analogy I would especially like to invoke refers to the attention-to-wording function of triggers like the particle *quote*, which a “speaker can insert ... just before citing a particular utterance” (Talmy forthcoming:58) and which selects out a particular concomitant of a constituent's referent from the local linguistic environment. And while for *quote* the concomitant is “the specific selection of morphemes in their particular sequence” (Talmy forthcoming:58), that is, their exact wording, in the case of *for example*, it would be the specific informational status as an exemplification—or with reference to Talmy's suggestion: The reader's attention is directed to aspects of linguistic organization or of their own cognitive processing.

Talmy convincingly motivates the use of *quote* with reference to Gricean principles¹³; likewise, such conversational maxims (or any other social or stylistic norms) may plausibly uncover some motivation for cases like (18)'s *for example* (reprinted here again):

(18) *Some of these [words] answered to their specific needs and interests—for example, squatter, clearing, foothill, watershed, congressional, sidewalk—but there were thousands of others but there were thousands of others that had no close connection to the American experience as such ...*

The author may, in exemplifying, well feel that, for some (expert) readers, an alleged ‘second’ linguistic representation could amount to a face-threatening act, since the ‘main’ text and the exemplification are supposed to convey the same referential content, conceptualized intensionally first, and then extensionally specified. In the present context, the analogy would basically rest on this line of argument: English settlers in North America rapidly develop their own characteristic forms of speech, retaining words from England, giving new senses to old words, freely borrowing from contact languages, and coining new ones (cf. Nunberg 1999:9f); and this last statement now receives evidential support (which an expert reader definitely would not need, especially given that *there were thousands of others*), in that the author adduces some exemplification: *squatter, clearing, foothill, watershed, congressional, sidewalk*. The specific parenthetical form, typically associated with incidental information to

¹³ A similar suggestion is already found in M. Lampert (1992:78ff). And to offer the original analysis: Talmy's (forthcoming:59) examples are *So she said to him, quote: You need to take a bath.* vs. *So she said to him that he needed to take a bath.* In the first example “this particle directs the hearer to attend not only to the overall referent of the expression that follows, but especially to its exact wording—that is, the specific selection of morphemes in their particular sequence. The speaker typically intends a certain function in directing attention this way. He believes that roughly the same referential content could have been evoked by a different expression closer to Gricean maxims or to social or stylistic norms. But he feels that the actual utterance, by virtue of its particular selection of words and their placement, diverges from that ideal in some direction. This could, for example, be in the direction of bluntness, hyperbole, odd affect, or legalistic caution. By using *quote*, the speaker intends to alert the hearer to such a divergence. In [the first example] this divergence is presumably the bluntness of the remark. By contrast, when the utterance is represented as indirect speech, as in [the second example], the construction directs the hearer's attention to the same semantic content, but not to any special effect that the speaker might feel the original wording engendered.”

be disregarded and hence most probably invoking the ‘asideness’ connotation, proves an appropriate means of conforming to the politeness principle (i.e., following a social norm) in a communicative situation of various, even opposite reader demands. Such strategy has thus, in the case of academic prose, gained the status of a register-specific text ‘move’ from intensional exposition to extensional qualification: Confronted with (potential) readers¹⁴ who would need the ‘repetition’ to reconstitute the author’s intended information and experts who are immediately able to retrieve some of the words listed, the author, in expressing the designated reading explicitly, alerts the readers to this distinctive informational status, here an exemplification. The reader is invited to direct their attention to what I would like to conceive as an organizational concomitant of the text to be processed: The dedicated trigger *for example* makes explicit the informational organization of the text, more specifically the relation between the progressing line of argument and the sequence to follow, i.e., the parenthetical target, and instructs readers to engage in a specific form of cognitive processing: ‘read it as an example not as an independent, self-contained statement contributing to the text(ual) progression’. And this means that rather than exclusively attending to the direct referring function of the lexical items like those enumerated in (18), the reader is assigned to also direct some attention to their concomitant function as examples, hence to the meta-linguistic status of text organization in terms of exemplification. Whether the parenthetical target thus specified is attentionally attenuated or activated seems (exclusively?) a matter of higher-level text functions, including a complex of interacting situational characteristics (cf., e.g., Biber 1988:28-58) and, ultimately, as a unique interaction between the given text and an individual reading experience, probably with no a priori generalizations possible.

6. THE RESEARCH AGENDA: SKETCHING AN ATTENTIONAL PROFILE OF (THE) PARENTHETICAL CONSTRUCTION(S)

In light of the exposition so far, it indeed turns out unquestionable that without recourse to an encompassive analytical framework informed by a sophisticated theory of language-specific attentional parameters any sensible investigation of parenthetical constructions proves pointless. The basic (strong) claim, then, is that parenthetical constructions are a linguistic phenomenon that is ‘simply’ defined by (a selection of) attentional mechanisms, which, just like Talmy’s model assumes, systematically interact in various forms of reinforcement, competition, and conflict to yield a(n) attentional profile(s).

At the same time, my sketch may have revealed that it is highly questionable to adhere to the ‘traditional’ view (or, rather: bias) that presupposes far-reaching shared cross-modality commonalities of the parenthetical construction, or considers the written modality even being parasitic on the spoken modality (reflecting the conditions of speech as well as it can).

What is in fact common to all parenthetical constructions to be perceived as such, irrespective of the modality, is that there is a vital, perceivable difference between them and the linguistic environment; otherwise there would not be a parenthetical construction at all. Hence the distinctness of parenthetcity must become (sufficiently) salient for addressees: In the spoken modality, the parenthetical delivery may well serve as a convenient dedicated

¹⁴ This suggestion appears to be in line with Nunberg’s (1990:109) “presumptive reader” and also compatible with Bredel’s (2008:147ff) “covert/overt writer”.

trigger to mark off parts of utterances as parenthetical. Yet research has also observed that the parenthetical delivery may (regularly?) ‘dissolve’, as in the case of some parentheticals (especially) in casual speech. This behavior may, however, directly follow from the type of devices available in (and native to) this modality: Vocal dynamics only allows for gradient modifications like reduction in loudness and shift in pitch, which by their very nature are intrinsically less distinct. In the written modality, by contrast, a set of discrete devices is conventionalized as dedicated triggers that ‘pop out’ as different from their environment, though with different degrees of clarity: Monofunctional parentheses are most successful in performing this task, and this is perhaps why they are generally acknowledged as the prototype; dashes fare less well in discriminating parenthetical constructions from their environment—unless they occur in pairs, representing the syntactic inclusion type of constructional slotting. Polyfunctional commas, even in the inclusion type, are the least felicitous devices to unambiguously indicate parentheticity; this becomes very obvious in the case of German relative clauses, where it would be necessary to use a more ‘prototypical’ device than the comma to unequivocally designate the parenthetical quality if desired.

In fact, in a cross-venue comparison of the criterial components, the modality-specific differences of parenthetical constructions appear to be more salient than the commonalities: First, the parenthesizers in written language employ a different kind of triggering device—they delimit and mark off a sequence (and its referent) twice, in advance and in retrospect, as distinct from the (preceding and following) linguistic environment, while in spoken language the device of parenthetical delivery is coextensive to and simultaneously ‘performed’ with the temporal extension of the complete parenthetical sequence’s utterance, manifest in the overlay of the parenthetical delivery. The parenthesizers, by contrast, occupy a separate ‘space’ before and after the parenthesized sequence, and thus parenthetical constructions in the written modality display a clear pattern of successiveness due to the modality’s strict(er) linearity—they do not establish a co-spatial layering.

Parenthetical targets, when considered for the attentional effect(s) predicted by their triggering devices, would, following the received view, be biased toward a cross-modality pattern that results in a general attenuation of their referents. However, the attentional implications rather seem to be quite different across the modalities; and again these attentional differentials follow from categorical differences in the production circumstances: A generally hypothesized attenuative effect on the referent of the parenthesized sequence, I claim, would fall short of accounting for the (variety of the) construction’s communicative purposes in the written modality. As has repeatedly been noted, the precise identification of the actual attentional effect(s), whether attenuating or activating, has recourse to higher-level functions of text organization and, hence, would presuppose a coherent semantic theory of text organization, which is, however, unavailable to date (cf. also Nunberg 1990:102). Also, as the few examples from the ‘corpus’ have demonstrated, the range of both the structural variety and the complexity parenthetical constructions allow (especially in the more formal registers of written language) corresponds to the categorical differences of situational features, like the opportunity (and the expectation, indeed) of deliberate planning and multiple revising of texts as against spontaneous interactive discourse—which is expected to feature more prefabricated sequences like the parentheticals or short comment clauses. The sophistication that parenthetical constructions manifest in written language appears to directly disprove another generally held prejudice, namely that this constructional option is an ad-hoc

‘remedy’ for an author’s negligence or even inability to follow a logical line of argument (cf. e.g., Bredel 2008:146).

Provided the attentional analysis of specifiers suggested in 5.5 is plausible, this subtype of parenthetical constructions would testify to a commonality between spoken and written language, which here would not differ both in terms of the devices they call for and in the attentional effects expected: Irrespective of the modality, *for example* as a dedicated form lexicalized to select out a concomitant aspect of the target’s referent would specify the same relation of exemplification between the non-parenthetical environment and the parenthesized sequence.

To round off the exposition so far, I will sketch a provisional attentional profile (cf. M. Lampert 2009) of (the) parenthetical construction(s) with reference to Talmy’s (forthcoming:7-16) Area Aa2, The generalized form-semantics association of a construction, which critically assumes “the irreducibility in the association between its form and its semantics” (Talmy forthcoming:8), “a construction’s capacity for constraint and optionality” (Talmy forthcoming:9), and a “consequent property of a construction to relate a family of similar forms to a family of similar meanings” (Talmy forthcoming:14), hence “association”. In the following, only some aspects from Talmy’s analysis are addressed, but any precise inspection remains yet to be done.

As to their generalized form, the following variants constitute the inventory of options in form types and thus illustrate the combinatorial variation in parenthesizers, along with their constraints by syntactic slotting. Again, for reasons of space, the parenthetical formats beyond the sentence are disregarded, and the construction’s generalized form is only detailed for the parenthesizers, with their slots exclusively representing the categories of the constituents. (Note that bold-faced items are obligatory and the bracketed items, i.e., the ‘category name’ dedicated verbalized trigger and the following comma, are optional constituents.)

- (i) ([dedicated verbal trigger[,]] **target**)
- (ii) ([Dedicated verbal trigger[,]] [**T**]**target**)
- (iii) —[dedicated verbal trigger[,]] **target**—
- (iv) , [dedicated verbal trigger [,]] **target**,
- (v) —[dedicated verbal trigger[,]] **target**.
- (vi) , [dedicated verbal trigger[,]] **target**.
- (vii) . [dedicated verbal trigger[,]] **Target**—
- (viii) . [Dedicated verbal trigger[,]] [**T**]**target**,

Parentheses regularly manifest the syntactic inclusion type, they may embrace (a) complete sentence(s) with (a) full stop(s), and there are no blank spaces between them and the parenthesized sequence(s); cf. (i) and (ii), which represent the case of a parenthesized complete sentence. The English pattern allows for an n- or m-dash as well as two ‘hyphens’, in the syntactic inclusion case, either with two blank spaces ‘embracing’ the dashes or not (see iii), while the commas in (iv) are regularly followed (but not preceded) by one blank space. For the relative positioning type, a complex pattern of interactions emerges: An ‘opening’ parenthesizer is obligatory, which in sentence-initial positions is conceptualized as being ‘co-entailed’ (or, following Nunberg 1990, ‘absorbed’) in the preceding blank space and capital letter. In sentence-final position, a complementary situation holds: An obligatory ‘closing’ parenthesizer is again ‘co-entailed’ (absorbed) in the following conventionalized full

stop (question mark or exclamation point). To detail the patterns for the individual parenthesizers: Blank spaces may or may not occur before and after the dash in sentence-final and -initial positions respectively, and a full stop without a blank (see v), while a blank space is required after the comma, as in (vi). After a preceding full stop in the case of a sentence-initial parenthetical construction, the dash may again be ‘embraced’ by blanks (cf. vii); sentence-initial parenthetical constructions marked off with a comma have no blank space before but after the comma, see (viii). (Note that the order of the patterns may be suggestive of a probable attention-driven hierarchy, with the parentheses yielding prototype effects.)

In view of its generalized semantics, I will only mention some selected aspects of (the) parenthetical construction(s), since a detailed analysis would certainly afford a book-length treatment, just as Talmy (forthcoming:14) states after a brief sketch at the beginning of his study: “A construction’s generalized semantics covers much more than described here, such as relating successive parts of a discourse (e.g., anaphors), relating morphemic content to the surrounding context (e.g., demonstratives), and directing greater or lesser attention to one or another entity, the subject of this book.”

The crucial question, then, that is likely to arise in this context is why parenthetical constructions exist in the first place. One reasonable suggestion may be that, as a meta-cognitive device, they establish an additional (separate?) text level, hence circumvent the linearity constraint of the linguistic medium’s spatial two-dimensionality and then associate, as a general cognitive parameter, divided attention—that is to say, they convey two ‘messages’ at a time, or, as Nunberg (1990:115.116) has it, parenthetical constructions, like quotations, “depart from a presumptive text”. If attenuation as a general feature were retained, it would mean that, in writing, parenthesizers instruct readers to direct some attention away from the default processing of a text in terms of developing a topic coherently in a linear form of progression. At the same time they would direct some attention to a currently relevant communicative purpose ‘outside’ this ‘running’ line of argumentation or information structure, that is, to the ‘inside’ of the parenthesizers, conveying some information with a distinctive status. (Note the parallel formulation to Area Ca4, above.) In case there is a specifier, this special status is verbalized—otherwise the reader will have to infer the relation between the two levels of text organization and their cognitive processing.

With different parenthesizers at separate linguistic ‘levels’—all having their structural constraints and distinct attentional effects—the inventory calls for detailed and differential same- and cross-venue comparative analyses specifying their attentional (and functional?) impact: Parentheses operate in morphemes and beyond, up to the paragraph-level; dashes are only admissible beyond morphemes and are limited by the sentence level; commas are only found above the morpheme and below the sentence level; and foot-/endnotes presuppose the whole text as domain. In general, parentheses will attract more attention to themselves than, say, commas, because of their physical qualities and their functional characteristics. Hence, there is, first, a distinction in their own attentional values: Differences between the parenthesizers may be arranged (though discretely) along a scale, giving rise to a hierarchy of triggering devices with prototype effects. Whether there is some other cognitive dimension intrinsic (?) to the shapes according to which parentheses, dashes, commas could impose gradience (analogous to the magnitude dimension in parenthetical delivery) awaits exploration. Second, it remains an open question, too, whether, and if so how, this attentional difference is ‘transmitted’ to their targets; i.e., they will differentially be affected and thus differ in the potential to be perceived as parenthetical.

And, finally, with reference to Len Talmy's Linguistic Attention, there are two critical questions: Whether a modification or accommodation of the 'spoken' factors proves sensible that will then account for the conditions of parenthetical constructions in the written modality; or whether a major reanalysis of the factors subserving the relative autonomy of the 'written' subsystem is called for—suggesting, in a somewhat larger perspective, an attentional (sub-)system for written language in general which would be based on the evidence that the attentional profiles follow from categorically different production circumstances (and their effects on reception).

Chapter 81

THE SOCIALLY EMBEDDED AND DYNAMICALLY EMBODIED NATURE OF METONYMY'S PROTOTYPICALITY

Kent Hill

Seigakuin University, Japan

ABSTRACT

The social and embodied nature of language has recently been making strides into the understanding of language use and development (Geeraerts, Kristiansen and Peirsman 2010; Feldman 2008). This paper attempts to build upon and further integrate these perspectives by looking at metonymy from a sociocognitive (Hill 2006) as well as dynamic perspective (Spivey 2007). Firstly, Geeraerts' (1997) diachronic analysis of prototypicality and Peirsman and Geeraerts' (2006) prototypical patterns of metonymy are outlined in the context of the Peirsman and Geeraerts (2006) and Croft (2006) exchange regarding whether metonymy's part-for-whole relation is one of association or contiguity. Secondly, using metonymy as the principle example, this paper proposes that communication is socially embedded through intersubjectivity and joint attention. Thirdly, it suggests the part-for-whole function of metonymy may also be similar to the whole-within-whole principle found in a *holon*. Fourthly, it proposes that this function is related to the dynamic complex systems principle of self-organization and that it acts to embody brain-body-environment triads. As such, the addition of more socially embedded and dynamically embodied grounding to metonymy's typical cognitive analysis in turn also suggests a similar triadic representation (i.e., dynamic socio-cognitive). Additionally suggested is that the understanding of prototypicality can benefit from being rendered as part of the dynamic process of the continuity of the mind, or as an *attractor landscape*. This paper concludes with the proposal that the socially embedded and dynamically embodied nature of metonymy's part-for-whole or whole-within-whole prototypicality is an instantiation of the ability to off-load cognition onto the environment.

Keywords: metonymy, prototypicality, embedded, embodied, cognitive, social, dynamic, intersubjective

1. INTRODUCTION

The socially embedded nature of language has recently been making strides into the understanding of language use and development. For example, Geeraerts, Kristiansen and Peirsman (2010) claim the basic architecture of language is recognized by cognitive linguistics as involving not just cognition, but socioculturally situated or embedded cognition. Additionally, Robinson (2010) found that a *socio-cognitive* approach enables researchers to trace flexibility step-by-step, or speaker-by-speaker, until seemingly “meaningless” individual variations actually show real development of meaning in time.

A view of cognition as embodied and embedded in brain-body-environment triads has also been gaining ground in cognitive linguistics (Gomila and Calvo 2008). Indeed, Feldman (2008) states that human language and thought are crucially shaped by the properties of our bodies and the structure of our physical and social environment. Moreover, abstract and metaphorical thought grows out of concrete everyday embodied experiences and grammar consists of neural circuitry pairing embodied abstract concepts with sound (or sign). In general, what is meant by embedded or situated is the role played in an agent’s behavior by its ongoing interactions with its immediate, in this case social, environment. Embodiment, in contrast, concerns the dynamic role of the physical properties of an agent’s body in its behavior (Beer 2008).

Dynamic approaches, which emphasize the temporal dimension of behavior and seek to apply the concepts and tools of dynamical systems theory to the analysis of agents, are as well influencing cognitive linguistics. As a result, usage events are being analyzed as to how they define and continuously redefine the language system in a dynamic way. Every usage event may then slightly redefine a person’s internal language system. As a dynamic point of departure, Spivey’s (2007) continuity of the mind thesis maintains that rather than focus on intermittent moments when the brain’s pattern of activity may be brushing up next to an identifiable discrete mental state or prototypical representation, it instead focuses on the continuous goal-oriented trajectory that the mind travels through when assessing the set of possible brain states. As we shall see in Geeraert’s (1997) diachronic analysis of prototypical semantics, a dynamic construal may be of benefit, especially in the context of metonymy.

This shift in descriptive format—from objects to events, from things to processes, as Spivey (2007) points out, has radical consequences for just about every conventional theory in the cognitive sciences. It means that the vast majority of the mind’s time is spent *in between* identifiable mental states rather than *in* them. Prototypicality may then be seen as the end result of a continuous dynamic process which may never actually be consciously or attentively attended to. It can then be accounted for in terms of neurological self-organization processes, not the postulation of explicit representations or static schemata (Gomila 2008).

From a dynamic complex systems framework (Gomila and Calvo 2008), a brain-body-environment triad as socially embedded and dynamically embodied views cognition as being:

- 1) situated
- 2) active
- 3) time-pressured in real-time (i.e., self-organizing)
- 4) one with the environment (i.e., organisms-environment systems are the proper units of analysis, not organisms as such)
- 5) off-loaded or schematized onto the environment

The remainder of the analysis of metonymy's prototypicality as socially embedded and dynamically embodied is presented in the following sections: diachronic prototype semantics, metonymy's prototypical patterns, metonymy as socially embedded, metonymy and holons, metonymy as dynamically embodied, examples of socially embedded and dynamically embodied metonymies, and off-loading cognition onto the environment.

2. DIACHRONIC PROTOTYPE SEMANTICS

Though not always in direct reference to metonymy's prototypicality, Geeraerts' (1997) analysis of diachronic prototype semantics nonetheless has many principles that can be applied to a prototypical analysis of metonymy, which, although a somewhat static depiction, does have dynamic elements that can also be enhanced from the application of a dynamic complex system perspective. According to Geeraerts (1997), a prototypical category shows an increasing flexibility. The core of which remains intact, but the fringe area grows and allows for broader and broader variation. From the core or nadir, prototypicality moves further from the center and around this hard conceptual core peripheral nuances arise. Prototypicality is therefore flexible enough to adapt to the continuous changes of context. It combines structural stability with flexibility. It does not change its overall structure to cope with new circumstances. Again, as we shall see, from this description the visualization of a prototypical category has much more in common with the understanding of a dynamic *attractor landscape* than with, perhaps, prototypical patterns.

Additionally, Geeraerts (1997) does note the dynamic nature of the synchronous notion of prototypical concept organization and recognizes that conceptual categories are not rigidly defined. Rather, he claims they combine a number of nuances through the centralizing action of a conceptual kernel or core, which implies the possibility of dynamically actualizing the prototypical concept in new peripheral uses. To sum up his perspective, the multiple possible actualities of a prototypical concept mark it as an inherently flexible, dynamic structure.

3. METONYMY'S PROTOTYPICAL PATTERNS

Peirsman and Geeraerts' (2006) analysis of metonymy stems from a view that there is conceptual contiguity between two relations within a domain or domain-matrix and they classify the core part-for-whole metonymical category into prototypical patterns (see Figure 1). Croft (2006), on the other hand, does not see the relation as contiguous but as associative.

This section takes up the Peirsman and Geeraerts (henceforth P and G)/Croft debate and discusses the cognitive exclusion of social factors from the analysis of metonymy. Following Ruiz de Mendoza Ibanez and Diez Velasco (2003), and Lakoff (1980), PART-FOR-WHOLE or WHOLE-FOR-PART summarizes the principle types of conceptual metonymies:

3.1. Domain Highlighting/Reduction

3.1.1. *We Have to Fill Up the Car with Gas*

The interpretation of the *car* as “gas tank of car” involves the highlighting of the domain of fuelling in the domain matrix of [CAR] as well as a constraint to the relevant part of the car. This is called *domain highlighting*, since the target-in-source metonymy makes a primary domain that is in the literal meaning.

Figure 1. The prototypical category of metonymical patterns.

3.2. Domain Adjustment/Expansion

3.2.1. *The Ham Sandwich Wants a Side Salad*

In order to achieve the semantic coherence specified by the unity of domain, there often occurs an adjustment of the domains of the individual words in the construction. Domain adjustment is the other major factor for source-in-target metonymies.

3.3. The P and G/ Croft Exchange

Croft (2006: 320) states, “Contiguity is an inferior description of metonymy in comparison to association, the traditional definition of metonymic semantic relations, since contiguity unlike association implies a notion of spatial nearness, and we have seen that nearness is inadequate.” Indeed, it can be difficult to differentiate the meaning of *contiguity* and *association* as they can often be synonymous. Once the construct of intersubjectivity is introduced, however, the terms can be distinguished by making *contiguity* the social-contextual relation (i.e., the proximity or salience of the object in context) and *association* the cognitive process (i.e., metonymy as conceptual). When these cognitive and social relationships intertwine, it results in the part-for-whole linguistic metonymy that

syntagmatically develops from a relative clause (i.e., *the customer who ordered the ham sandwich*) which then becomes the subject of the sentence (i.e., *the ham sandwich wants a side salad*).

In the P and G/Croft exchanges, in order to argue for the associative position, Croft (2006) provided what he considered to be unacceptable examples of metonymy and these also illustrate how a broader social perspective of joint attention can assist in the acceptance of a metonym.

3.3.1. Location for Located

**The dining room ate dessert*

P and G observe that some of Croft's "ungrammatical" examples sound perfectly natural when they occur in an appropriate context. If you are throwing a big dinner party with hundreds of guests in various rooms, for example, you may very well say that the *larger dining room is already eating dessert, while the smaller is still at the main course*. Thus, the meaning or construal of the metonymy is also dependent upon the contiguous intersubjective or joint-attention focus between these interlocutors who are throwing the party. The construal also allows for the elision of *dining room* in the second instance to simply *smaller*. Context is elided to the most salient part and, hence, elision, similar to metonymy, influences how the cognitive association (i.e., PART-FOR-WHOLE) develops into a conceptual metonymy (e.g., ORDER-FOR-CUSTOMER). Additionally, it is this shared intersubjective context or a mutual assumption shared by the listener from the speaker's implication that determines whether the metonymy is acceptable or not.

The following are additional suggested contexts for other acceptable and unacceptable Croft examples:

PART-FOR-WHOLE

a) **I painted the drawer*. – The drawer in this example is intended to represent the desk. However, a drawer is not the intersubjective focus of a desk in that it could mean different things to different people. According to Ruiz de Mendoza and Mairal (2007), the Correlation Principle is violated here in that from the context the drawer is not of most relevance. Perhaps more to the point, this example may work better as an event metonymy rather than a referential one (Dirven 1999). Consider: *I drawered the document* as compared to **I desked the document*.

WHOLE-FOR-PART

a) *We have to fill up the car*. – "Gas" is the intersubjective focus here but, depending on the joint-attention focus, it would also be possible to fill the seats with people or the trunk with presents (cf. *The car is empty*). That is, whole-for-part could be used in different contexts.

b) **The house burned down*. [for just the dining room] – This example is similar to the unacceptable use of *desk*. However, in this case, the use of *down* indicates fully or completely and therefore what burned could not simply be a part of the house (cf. *The house burned*.) Furthermore, the intersubjective focus of a house is that it is generally understood to be a compartmentalized yet structurally intact unit; however, this is not necessarily the case with cities. Thus, whole-for-part may or may not be acceptable with a house, but is with cities (e.g., *L.A. is burning*).

CONTAINER-FOR-CONTAINED

a) **The glass is red.* – [for wine] In this case, one cannot say *The glass is red* to mean *The wine is red* because it could refer to the glass and hence have more than one meaning. But note that *red* can still be a metonymy in the following example: *The red is delicious* (i.e., PROPERTY-FOR-OBJECT).

The reasons why these metonymies are problematic but not necessarily unacceptable are that they could have more than one meaning, mean different things to different people, or mean different things in different contexts. The main point is perhaps that they are too literal and not embedded enough within a social context to be acceptable. Without some further form of socially embedded target-in-source figuration, it is difficult to associate the underlying target with the appropriate contiguous contextual source.

Other cognitive linguists have tackled whether the metonymic relation is a mapping of contiguity or association. Feyaerts (1999) opposes contiguity as the essential feature of metonymy because of different kinds of functional-associative relationships such as *cause-and-effect* and *object-property*. Consequently, he seems to prefer Croft's use of associative. However, there is a danger of circularity here in that cause-and-effect is one of the patterns found in P and G's prototypical definition which favors contiguity (see Figure 1). Blank (1999) distinguishes association and contiguity by introducing paradigmatic (i.e., associative) and syntagmatic (i.e., contiguous) relations. Blank (1999: 174) then stresses that metonymy has a clear-cut cognitive background, yet adds an intersubjective perspective to his explanation: "The only things speakers have to share are the same conceptual relations, common world knowledge about how life is typically organized and how the 'things of life' are interrelated. This makes metonymies very efficient tools for resolving different tasks in communication."

Other cognitive linguists prefer to analyze the target-in-source or source-in-target relation of metonymy in terms of pragmatics. Fauconnier (1997) states that the manipulation of space configurations in the absence of a real-world matchup would be no more than a "solipsistic" exercise were it not for the crucial implicit assumption that we know in principle how to match configurations. He assumes the real-world matchup involves a combination of pragmatic and grammatical factors that make the appropriate "domain type" accessible. Exactly how this occurs, however, he affirms is at present an unsolved (although unavoidable) problem. Yet, in context, he continues, there is no trouble in telling what the domain type is, although how it is, is still far from understood. From a sociocognitive perspective, Fauconnier's analysis suggests that how access to the appropriate domain type may be achieved between interlocutors is through their intersubjective perspective, which is socially embedded and which develops *shared* space configurations.

Gibbs (1994) and Barcelona (2007) advance the understanding of how domain types are schematized, or socially embedded, through the introduction of *scenarios*. People metonymically utilize subparts of, for example, a restaurant ordering scenario in order to stand for the whole scenario. Listeners, having internalized the scenario, readily recognize that speakers intend them to understand the entire scenario when one subpart of it is stated, because, according to Gibbs, they share the same cognitive model, or perhaps prototypical patterns. Song (1998) demonstrates how the joint focus of a metonymy can function deictically, similar to the gesture of pointing. For instance, in actual conversation, deictic pointing can be achieved when the metonymy acts as a subject: *The ham sandwich wants a side salad*. Song's analysis also includes the perspective of the listener in that the use of a

metonymy may encourage the listener to search for further contextual effects. The reference of *the ham sandwich* to the customer may for instance also have the social implication that the speaker intends to make manifest an assumption in the listener that he is looking down upon his customers, which also assumes the showing of some intimacy towards the listener. According to Song, the embedding of this kind of affective mutuality between interlocutors outweighs the extra processing effort incurred by the use of the metonymy. *The ham sandwich* metonym then represents a specialized lexicon for the socially embedded joint activity found in a restaurant. Clark (1996) adds that every discourse community has a specialized lexicon of which metonymy may play a significant role.

Clark (1996) utilizes *equity theory* to make the point that when people find themselves in inequitable situations (e.g., as a server), they feel distress and the more inequitable the situation, the more distress they feel. To eliminate this distress they are motivated to restore equity. By equating customers with their orders, the server depersonalizes the customers and restores equity or saves face from having to serve them. The metonymy also works to exclude the customer from what Clark (1996) calls “inside information” and in this sense at least two different discourse communities exist in restaurants (i.e., between the staff and between the staff and customers). Therefore, the frequent usage of metonymies is also an indication of different socially constructed and embedded discourse communities.

Since *the ham sandwich* can be a property that characterizes the customer most effectively to the server, Seto (1999) suggests that it is one of the reasons that prompt some scholars to adopt a broader, possibly more social, definition of metonymy. Additionally, Warren (1999) provides an insightful perspective in that it should not be forgotten that metonymy is a kind of semantic-syntactic construction, comparable to, for instance, compounding and genitive constructions, which a language user has to learn to interpret and form to reach full competence. In this sense, metonymy construction and usage is more than a cognitive function; it is also a necessary component of sociocultural communicative or interactive competence.

Kovecses and Radden (1998) clearly state the need for the addition of a social factor in the analysis of metonymy, although their analysis also highlights the need to find commensuration between cognitive and social views: “some prototypical forms of metonymies may ‘default’ for social, communicative or aesthetic reasons.” Social considerations in a communicative situation, they continue, may require speakers to “override” some cognitive principles. The goal of establishing sociocognitive bases for metonymy, contrastively, is to argue that what is occurring is not defaulting or overriding. It is simply necessary to learn how these cognitive and social principles interact and to find commensuration between them because metonymy’s analysis cannot be fully explained by only one or the other view. Both are required. Indeed, it may not be possible to analyze metonymy without the use of both of the terms *association* and *contiguity*. To sum up this section, in terms of metonymy this paper views *contiguity* as spatiotemporal and actions/events processes (i.e., body) and *association* as cognitive part-for-whole processes (i.e., brain). In this sense, both association and contiguity are necessary for a metonymy’s acceptability and it is both the cognitive and social nature of communication in context which establishes awareness of the underlying implication of a metonymy and which disambiguates the variations in its interpretation, leading to its acceptability.

4. METONYMY AS SOCIALLY EMBEDDED

Since metonymy's prototypical patterns cannot be simply viewed as the internal workings of only one individual, both a joint-attention frame and intersubjectivity are useful to explain how these patterns work in context so that multiple interlocutors are able to attune to the intentions of others. A joint-attention frame involves triadic interaction mediated by an object in which two participants constantly monitor one another's attention to it and themselves (Tomasello 2003). To illustrate, when considering the case of the *ham sandwich* metonymy, the *ham sandwich* grammatical subject as a reference to a customer is much more likely to be used between two waiters or a waiter and a cook because of the salience of the *ham sandwich* object which passes between them and which then becomes socially embedded into their context. Possibly as a result of mirror neuron activation (Gallese 2003), intersubjectivity concerns practices that involve a perceptual sense of others and that constitute a common bodily intentionality shared by both the perceiving subject and the perceived other (Gallagher 2008). In the case of the *ham sandwich* metonymy, it represents the abstracted (i.e., ORDER-FOR-CUSTOMER) part-for-whole result of an embodied joint-attention frame (see Figure 2). If the waiter implies the *ham sandwich* metonymy in reference to the customer because they are contiguous to both the order and customer then the cook assumes the association between the customer and her order.

Figure 2. The ham sandwich joint-attention frame.

According to Nunberg (1995), the description of these mechanisms is fundamentally a linguistic problem, rather than a problem of conceptual analysis. Cases like this, he continues, can be thought of as “occurrent metonymies,” where the relation between two domains can

only be exploited in a restricted range of situations or environments (e.g., a restaurant or kitchen). That metonymy is a syntagmatic rather than conceptual relation can be suggested in the sense that to the waiter the price of a ham sandwich might be more salient if it is written on the bill along with the order, making the association between the customer, the order and the bill also that much more linguistically relevant (Sperber and Wilson 1986).

In this sense, the price may attract both customer and order and create their syntagmatic relationship. Indeed, *the ham sandwich* cannot stand on its own as a metonymy. It gains its meaning from the syntagmatic construction (Goldberg 1995). With other metonymic constructions, for example, *Nixon bombed Hanoi*, the bombing of Hanoi associates, attracts, or relates the *Nixon* metonymy with the US government. Rommetveit's (1992) sociocultural dialogically-based approach to communication and human cognition can be advantageously applied to metonymy. Two of his main principles are that a dyadic state of intersubjectivity with respect to some context is attained by verbal communication when:

- 1) some aspect is brought into focus by one participant and, as a consequence, jointly attended to by both of them (e.g., a *ham sandwich*)
- 2) when both participants take it for granted that each of them assumes the other to hold that implication (e.g., ORDER-FOR-CUSTOMER)

Both of these principles are realized through metonymy usage as a result of a shared intersubjective joint-attention frame in a socially embedded context. Figure 3 illustrates an embedded sociocognitive approach to metonymy in that P and G's prototypical patterns are not only cognitive (i.e., the box within self and other) but contextual and the joint-attention frame has also been socially embedded into the contextual environment. The joint-attention frame is in bold type and the contextual prototypical patterns are not.

Figure 3. An embedded sociocognitive analysis of metonymy.

5. METONYMY AND HOLONS

This section introduces the concept of a *holon* as a possible method to overcome the vagueness of the concept of a *domain*. By replacing or merging a holon with a domain and then mapping prototypicality patterns onto it, it is possible to form a hypothetically or intuitively more neurologically plausible dynamic complex system. A holon is a whole that is a part of other wholes. For example, a whole atom is part of a whole molecule; a whole molecule is part of a whole cell; a whole cell is part of a whole organism; and this whole-within-whole inter-connected network develops and extends throughout the universe. Reality is composed of neither wholes nor parts, but of whole/parts, or holons (Wilber 2001). Thus, metonymy, which is typically considered to be a part-for-whole or whole-for-part relation, might also be considered as a conceptual and linguistic instantiation of this whole-within-whole developmental network (cf. taxonomy and partonymy)—or as a holon. In this sense, association and contiguity as well as a balance between them are both necessary in the analysis of metonymy in order to fully express a whole-within-whole relation. Each successive contiguous whole-within-whole level evolves in time into a more complex level, which is what occurs through association (e.g., ORDER-FOR-CUSTOMER). In Figure 4, P and G's prototypical patterns have been mapped onto a five-level holarchy. To illustrate whole-within-whole as opposed to part-for-whole, in the context of the metonymy *head of the company*, we can only speak of the whole head and not the top part of the body. In this sense, it is a whole-within-whole metonymy.

Figure 4. Mapping prototypical patterns onto a holon.

5.1. Socially Embedding and Dynamically Embodying a Prototypical Pattern Hierarchy

In this section, we further embed and embody the five-level prototypical pattern holarchy within a brain-body-environment triad (see Figure 5). This results in a six-level holarchy (i.e., matter, brain, body, activity, social and environment). The prototypical patterns can then be mapped onto five of the six levels:

- 1) matter (i.e., bounded/unbounded)
- 2) brain (i.e., part-for-whole)
- 3) body (i.e., spatiotemporal: physical and emotional)
- 4) activity (i.e., actions/events/processes)
- 5) social (i.e., inter-subjective)
- 6) environment (i.e., assemblies/collections: inter-objective)

From the direction of the arrows in Figure 5, it can be seen that socially embedding is an internalization process through usage and dynamically embodying is an externalization process creating greater complexity. Prototypicality is the end result these of internalizing embedding and externalizing embodying processes.

Figure 5. An embedded and embodied brain-body-environment holarchy.

6. METONYMY AS DYNAMICALLY EMBODIED

The final concept to complement and provide further hypothetical neurological plausibility to the brain-body-environment holarchy is the concept of an *attractor landscape*. The notion of a trajectory through an attractor landscape is at the heart of Spivey's (2007) continuity of the mind thesis. The mediating representational space between sensory input and motor output is one that generates a continuously dynamic trajectory. The emphasis is on the journey, the process, the activity, not the destinations or objects. His thesis allows for the conception of intermediate regions in the trajectory that are visited *on the way* toward an attractor basin that approximates some interpretable pure mental state or what might possibly be considered a domain.

An attractor is a region of a system's state space into which the system tends to move (Larsen-Freeman and Cameron 2008). Within the brain-body-environment holarchy, this would involve attracting the trajectory to a part-for-whole or whole-within-whole relation between two of the six levels.

The closest this trajectory might come to prototypicality in Geeraerts' (1997) sense within an attractor before changing trajectory would be to brush up near its basin just long enough to bring that attractor's percepts and actions into prominence (see Figure 6 for a hypothetical depiction of an attractor landscape). In Figure 6, the smaller basins represent exemplars. The nadir or core of the large basin is the prototype or the "best" example of the concept, which may not even correspond to any object that has actually been experienced (Spivey 2007). Intermediate regions along the continuous trajectory are where most of mental life is spent not in easily labeled static mental states or domains.

Figure 6. A hypothetical attractor landscape blending prototype and exemplar accounts.

This dynamic depiction of an attractor, however, as opposed to a static depiction of prototypical patterns, does allow for the flexibility and peripheral instances found in Geeraerts' (1997) diachronic prototype semantics.

In self-organization, the system selects or is attracted to one preferred configuration out of many possible states, but behavioral variability is an essential precursor (Thelen and Smith 1994). Self-organization is the spontaneous creation of more complex order or activity; the result of which is a more complex structure which was not planned or managed by an outside source (Larsen-Freeman and Cameron 2008).

From a communicative context, PART-FOR-WHOLE and WHOLE-WITHIN-WHOLE are fundamental examples of self-organization cognitive processes which are also fundamental to the manifestation of metonymies. Seen from this dynamic complex systems perspective, prototypicality once again then represents not an initial state but the result of a combination of a continuous trajectory and dynamic self-organization processes.

6.1. A Metonymic Brain-Body-Environment Holarchy as an Attractor Landscape

The depiction of metonymy within a dynamic attractor landscape has made it possible to incorporate some of the dynamic elements from Geeraerts' (1997) diachronic analysis of prototypicality, which can adapt to continuous changes in meaning, and it has also removed some of the non-dynamic elements from P and G's prototypical patterns. As P and G (2006) note, a unitary definition of metonymy in terms of a semantic shift within a "domain" or a "domain-matrix" is far from unproblematic, given the relative vagueness of the concepts of domain and domain-matrix. Indeed, their prototypical patterns can also resemble what might be considered to be a domain-matrix, which unfortunately does not aid in reducing how domains are problematic. A dynamic depiction, on the other hand, though hypothetical, attempts to be more neurologically plausible at least intuitively.

Figure 7 shows a rudimentary mapping of the metonymic brain-body-environment holarchy onto an attractor landscape.

Figure 7. The brain-body-environment holarchy as an attractor landscape.

If we now attempt to map P and G's (2006) prototypical patterns onto the attractor landscape, bounded/unbounded (i.e., matter) could be found at the base of the attractor, which

allow for nuances in meaning (e.g., mass vs. count nouns). The part-for-whole pattern (i.e., brain) can be seen as the fundamental process of self-organization within the nadir of the large basin. Spatio-temporal patterns (i.e., body) are combined without distinction within the attractor landscape. Events/actions/processes (i.e., activity) are the result of the internalization of brain-body-environment triadic processes represented by the cause-and-effect trajectory in an attractor landscape.

Finally, collections/assemblies (i.e., environment) develop from the holarchical organization within the attractor landscape (e.g., exemplar or basic, super-, and sub- category levels). All of the levels together represent a whole-within-whole dynamic complex system. In general, then, a continuous trajectory through a brain-body-environment holarchical attractor is what is intended by the terms socially embedded and dynamically embodied.

7. EXAMPLES OF SOCIALLY EMBEDDED AND DYNAMICALLY EMBODIED METONYMIES

This section briefly provides examples of metonymies to support the view that it is the interaction of cognitive, social and dynamic factors in a brain-body-environment holarchical attractor that manifests metonymies and motivates metonymic constructions and that this interaction provides a better more inter-theoretical explanatory power to the analysis of metonymy. As Beer (2008) correctly points out, it is becoming increasingly clear that situatedness (i.e., embeddedness), embodiment and dynamics work much better as a unit. Combining these three areas leads to the notion of a brain-body-environment system, wherein an agent's nervous system, its body, and its environment are each conceptualized as dynamical systems that are in continuous interaction. Apart from the first level which is pre-embodied or pre-embedded, example metonymies from Lakoff (1980), Littlemore (2009) and the author are provided for each of the remaining five levels of the brain-body environment holarchical attractor:

1. Matter (i.e., bounded/unbounded)

- (1) mass vs. count nouns
- (2) present tense vs. progressive aspect

2. Brain (i.e., part-for-whole)

OBJECT FOR INTELLIGENCE (OR LACK THERE OF)

- 1) Grey matter
- 2) Noodle
- 3) A no-brainer

3. Body (i.e., spatiotemporal)

BODY PART USED FOR USER

- (1) Head of the company
- (2) A good hand
- (3) The eyes and ears of the company
- (4) Face time

OBJECT USED FOR USER – Embodied externalization from body

- (1) The sax has the flu today.
- (2) We need a better glove at third base.

EMOTION AS TEMPERATURE– Embedded internalization from environment

- (1) He gave me the cold shoulder.
- (2) She's hot under the collar.

4. Activity (i.e., actions/events/processes)

THING FOR THE ACTION – Embodied externalization of body

- (1) Legging it
- (2) Elbowing someone out of the way

ACTION FOR PERSON – Embedded internalization of action

- (1) Driver
- (2) Singer

5. Social (i.e., inter-subjective)

POSITION FOR SOCIAL STATUS – Embodied externalization of body

- (1) The man wants to see you now.
- (2) The suits who are in charge
- (3) Girl Friday

PEOPLE RESPONSIBLE FOR INSTITUTION

- (1) Nixon bombed Hanoi.

6. Environment (i.e., assemblies/collections: inter-objective)

ENVIRONMENT FOR THE INSTITUTION

- (1) Wall Street is in a panic.
- (2) If the upstairs don't get you the downstairs will.

Of note, level three (i.e., body) has both physical and emotional levels. Many ways of expressing emotion with metonymies seem to stem from the environment (e.g., TEMPERATURE-FOR-EMOTION). Again, each level extends to or dynamically embodies the next higher one creating greater complexity and each level is also socially embedded to the next one lower through usage.

Indeed, the manifestation of metonymy is then better seen as the result of more efficient brain-body-environment activity between interlocutors. Part-for-whole patterns (i.e., cognitive brains) interact with spatiotemporal patterns (i.e., socially embedded bodies) which in turn interact with actions/events/processes patterns (i.e., dynamically embodied environments). Hence, both cognitive-social-dynamic and brain-body-environment are similarly triadic and necessary to reveal how the manifestation of a conceptual-linguistic-activity metonymy is the result of more efficient part-for-whole or whole-within-whole self-organizing processes and the metonymy itself is in most contexts a more efficient method of expressing meaning. In the case of the *ham sandwich*, if the name of the customer in question is known to the restaurant personnel, then it might be more efficient, especially if more than one ham sandwich has been ordered, to refer to the customer by his or her name rather than

by the ORDER-FOR-CUSTOMER metonymy. Without knowing the customer's name, however, it is more efficient to rename the customer with his or her order similar to a deictic or genitive function. Referring to the customer by their order then requires less cognitive effort on the part of the waiter. In this sense, cognition has been off-loaded onto the environment.

8. OFF-LOADING COGNITION ONTO THE ENVIRONMENT

The final assertion stated in this paper is that the socially embedded and dynamically embodied nature of metonymy's part-for-whole/whole-within-whole prototypicality is an instantiation of the ability to off-load cognition onto the environment. If one sees the situation and what the agent is doing in it, and how the agent is doing it, and what the agent is expressing (e.g., through his or her gestures and style of movement), and this perception is already informed by one's own interaction with them and others, as well as by previous situated experiences, habitual ways of understanding, and cultural norms and established practices, then in cases in which one encounters normal ordinary engagements the work of understanding is already sufficiently accomplished and one does not have to go any further (Gallagher 2008).

One then does not have to start thinking about what might be going on in the other person's mind since everything one needs for understanding him or her is there in his or her action and in the intersubjective shared world—and metonymies reinforce this shared understanding in action through their more efficient syntagmatic construction.

This contiguous activity between interlocutors assists in dynamically embodying the environment as part of the mind. These patterns of activity and discourse are inter- and intra-cognitively internalized and externalized in a dynamic brain-body-environment holarchical attractor.

The utilization of these cognitive tools into brain-body-environment triads blurs the line between social embeddedness (i.e., co-interaction in the environment perform processes of cognition) and dynamic embodiment (i.e., the body's sensors help perform cognition processes) which in turn allows for them to be off-loaded onto the environment. A cognitive "schematization" of the environment in a part-for-whole or whole-within-whole pattern is the result of this more efficient activity between brain-body-environment triads, which is abstracted in language and used as a metonymic form of expression. Cognition as socially embedded and dynamically embodied onto the environment means the information found in a metonymy may not always cognitively represented (Gomila and Calvo 2008). Instead, the construction or syntagmatic context can be counted on to imply some of the meaning. This metonymic network represented in off-loaded cognition onto a schematized environment thereby facilitates minds that are quite possibly larger than themselves.

8.1. Brain-Body-Environment Schematization

From a brain-body-environment perspective, it is not the mind which contains schemata as such. Instead it is the brain-body-environment triad, especially the environment, which becomes schematized according to a particular embedded and embodied perspective. For

instance, it is the restaurant or kitchen which is schematized or designed to function more efficiently and the *ham sandwich* (i.e., ORDER-FOR-CUSTOMER) represents a part-for-whole/whole-within-whole shared understanding from co-action between interlocutors in this efficiently schematized environment.

Similar to prototypicality, this environment must, however, still remain dynamic and be continuously adapting to changes in meaning to allow for more efficient methods of activity.

This is what is continuously happening when goal-directed self-organizing cognitive processes are off-loaded to schematize the environment, and metonymic expressions reflect this increased efficiency through their economical use of language to convey more concise meaning. Citing another example, with *The Times hasn't arrived at the press conference yet* the press conference has been schematized according to the different newspapers or publications attending the conference.

9. DISCUSSION

The mind is on a continuous and dynamic goal-directed path in both a concrete (e.g., food or shelter) and abstract (e.g., love or thought) sense. Abstract or metaphorical thought grows out of concrete everyday embodied experiences. The mind, apart from dynamic self-organizing processes and brain-body-environment holarchical attractors, does not necessarily require schematization because of its forward-looking goal-directed trajectory. It remains on its continuous trajectory rarely visiting what might be considered actual schemata or prototypicality but nonetheless motivating and manifesting metonymies.

This embedded and embodied orientation to cognition is what computational theories of language development should also possibly adopt. Computational theories of language development could utilize the brain-body-environment triad and be goal-directed in nature with action sequences that have schematized environments in order to more efficiently achieve a developmental goal.

Metonymy is always motivated by intersubjective principles of self-organization to create more efficient meaning in communication similar to the more efficient activity found in the environment. A metonymic construction is typically literal with only the metonym being used figuratively.

The levels of the brain-body-environment holarchical attractor are used to associate the figurative implication of the metonymy from the literal construction. These levels may also come into play with metaphor. In a further attempt to overcome some of the vagueness in regards to the term “domain,” Figure 8 illustrates how metaphor might also be depicted as the interaction of two brain-body-environment holarchical attractors.

Along with the terms *source* and *target* for metaphor, other cognitive linguistics terms such as *figure* and *ground* and *encyclopedic knowledge* are also compatible within the trajectory of one or more metonymic brain-body-environment holarchical attractors.

Figure 8. Brain-body-environment holarchical attractors and their relation to metaphor.

CONCLUSION

This paper views metonymy as a means of communicative expression representing shared understanding in language which developed from more efficient co-activity in the environment. Using metonymy and prototypicality as its principle examples, it has looked at communication from a dynamic sociocognitive perspective which attempts to establish that the cognitive analysis of communication benefits from being seen as socially embedded through intersubjectivity and joint attention and dynamically embodied through brain-body-environment triads. It views both terms association and contiguity as necessary in the analysis of metonymy. It introduced the concept of a whole-within-whole holon as a possible addition to metonymy's typical part-for-whole or whole-for-part analysis and it attempted to map P and G's prototypical patterns as well as a brain-body-environment triad onto it to create a brain-body-environment holarchical network. It has also attempted to construe prototypicality in dynamic terms of attractor landscapes, resulting in a brain-body-environment holarchical attractor. It has furthermore suggested that a cognitive-social-dynamic triad offers greater hypothetical neurologically plausibility to the explanatory power of the analysis of metonymy.

It concluded by proposing that this perspective allows cognition to be off-loaded onto the environment and by so doing the environment becomes schematized according to self-organizing inter-connected activity.

Chapter 82

PERCEPTION OF EMOTIONAL INTERJECTIONS

Åsa Abelin

University of Gothenburg, Sweden

ABSTRACT

The main question addressed is whether emotional prosody of interjections, which show a non-arbitrary – indexical – relation between expression and meaning, could be integrated in the lexical representation, and whether this differs between high-lexical interjections and low-lexical interjections. Swedish high-lexical interjections have a more defined semantic content and can be understood without prosody, for example, hurrah, while low-lexical interjections are more ambiguous and can't be understood without the appropriate prosody, for example, oh. Lexical decision experiments were performed with high-lexical and low-lexical interjections having matching or mismatching prosody. The main hypothesis is that mismatch will slow down reaction times, especially for the low-lexical interjections.

The results of the experiments show that (a) stimuli with mismatch between lexical content and emotional prosody were recognized more slowly than matching stimuli, (b) low-lexical interjections were recognized more slowly than high-lexical interjections in mismatching conditions. The stimuli words were analysed acoustically with regard to F0 variation and duration, to pinpoint whether differing reaction times are dependent on acoustic variables or whether they depend on the mismatch condition as such. The comparison between the reaction times and the acoustic analysis shows that (c) reaction times are partly dependent on the specific emotion: different emotions have different durations and reaction times. However, the durations were not correlated with reaction times in matching and mismatching conditions.

The conclusion is that it is the mismatching prosody as such which affects reaction times, and that low-lexical interjections are affected more by mismatch than high-lexical interjections. It is further claimed that low lexical interjections with different emotional prosodies are in fact not homonymous, or polysemous, but that they can be seen as different morphemes since they have different meanings and different forms. Interjections have a certain degree of emotional-prosodic specification in the lexical representation and emotional prosody is part of the phonological representation. Emotional prosody is thus part of the linguistic system, at the same time as the lexicon is not separated from other cognitive and communicative abilities, such as understanding and expression of emotional prosody in general.

Keywords: prosody, emotions, interjections, word recognition

1. INTRODUCTION

A special case of non-arbitrariness in language is emotional prosody. Emotional prosody is always present in interjections. The non-arbitrary relation between prosodic expression and meaning in emotional interjections is mainly indexical; the expression is caused by a bodily or mental reaction, but the prosody is also modified by language conventions. Emotional prosody is also partly similar in the world's languages (Abelin and Allwood 2002; Sauter et al. 2009).

To penetrate the question of the status of emotional prosody in interjections, two main types of interjection were studied: high-lexical interjections, having a more defined semantic content, for example, *hurrah*, and low-lexical interjections, which have a more vague semantic content, for example, *oh*. The meaning of a high-lexical interjection can be understood without hearing the prosody (e.g., in reading the interjection), while the meaning of a low-lexical interjection cannot. There are several possible interpretations of, for example, the phoneme string represented in writing by *oh*; with certain prosody it expresses sadness or disappointment, but with another prosody it expresses surprise. Could it therefore be the case that the prosody of low-lexical interjections belongs to the lexical representation, while this is not valid for high-lexical interjections?

The general question to be investigated is thus whether prosody of an interjection could be coded in the lexical representation or if it is more loosely connected to it, that is, added by processes at a higher processing level. The question is also whether different reaction times of lexical decisions are decided by the acoustic variables F0 variation or duration of the interjections and thus could be explained by different input, or, whether reaction times are decided by the mismatch condition.

The questions were investigated by performing lexical decision experiments with interjections having matching or mismatching prosody, in order to get at the role of prosody when listeners are interpreting interjections.

Hypotheses

Mismatch will slow down reaction times more for low-lexical interjections

Low-lexical interjections were recognized more slowly than high-lexical interjections in mismatching conditions.

Low-lexical interjections will be reacted to more quickly than high-lexical interjections

The stimulus words used in the lexical decision experiments were analysed acoustically. The results of the acoustic analysis were then analysed in relation to the outcome of the lexical decision experiments.

2. BACKGROUND

Sekiguchi and Nakajima (1999) found, in a priming experiment, that the prime activated only the representations of prosodically congruent words. They therefore concluded that Japanese listeners use lexical prosody for lexical access of their language and that the role of lexical prosody is determined language-specifically. The results of Sekiguchi (2006) suggest

that the constraint of lexical prosody is not so strong, but is affected by the factor of word-relative familiarity. The argument goes like this: What type of information constrains the activation of candidate representations in word recognition? Many models of spoken word recognition assume that the activation of word representations is constrained by segmental features of speech input. Although it is highly probable that the segmental feature is used for candidate activation, every word also has other features, for example, suprasegmental, prosodic features, which are given by pitch contour, amplitude contour, or temporal variation across segmental features. One of these is lexical prosody, and lexical prosody is therefore a possible constraint on candidate activation in lexical access of spoken word recognition. Other studies which suggest that word prosody is represented in the mental lexicon were made by e.g., Lindfield, Wingfield and Goodglass (1999).

The subject of emotional prosody being integrated in the lexicon has been studied by e.g., Nygaard and Queen (2008) who investigated the role of emotional tone of voice in the perception of spoken words and the question of emotional prosody being non-linguistic in nature or being integrated with the semantic content of spoken language. Listeners were presented with words that had either a happy, sad, or neutral meaning. Each word was spoken in a tone of voice (happy, sad, or neutral) that was congruent, incongruent, or neutral, and naming latencies were collected. Tone of voice was either blocked or mixed with respect to emotional meaning. Their results suggest that emotional tone of voice facilitates linguistic processing of emotional words in an emotion-congruent fashion. This suggests that perception of spoken words is not independent of the perception of emotional prosody, and that the integration of emotional tone of voice with linguistic content occurs during lexical processing. Similar conclusions are drawn by Wurm et al. (2012) in a study on sentences spoken in different tones of voice, with lexical decision tasks on sentence final emotionally congruent or incongruent words. They found that reaction times for congruent trials were faster than those for incongruent trials.

Nygaard and Lunders (2002) investigated the effects of emotional tone of voice on the perception of word meaning. In two experiments, listeners were presented with emotional homophones that had one affective meaning, happy or sad, and one neutral meaning, e.g., *flower/flour* (happy and neutral), *die/dye* (sad and neutral). In both experiments, the listeners were asked to transcribe the emotional homophones presented in three different affective tones—happy, neutral, and sad. The results showed that the listeners provided more affective than neutral transcriptions when the tone of voice was congruent with the emotional meaning of the homophone. They suggest that emotional tone of voice affects the processing of lexically ambiguous words by biasing the selection of word meaning.

Dietrich et al. (2006), in a study on German interjections, found that listeners classify data into two categories, interjections with high or low lexical information; the latter of these is more ambiguous than the first. They had participants respond to the question ‘Which emotion was expressed by the utterance?’ Participants heard stimuli spoken with a neutral tone and responded by pressing one of 5 buttons, thereby rating the utterances as neutral, happy, angry, disgusted, or sad. (This was not a reaction-time experiment.) The experiment resulted in percentage ratings of the stimuli in terms of emotional recognition rates for different emotional interjections, spoken in a neutral tone, and aimed at isolating the emotional lexical meaning of the words. In this way the distinction high-lexical interjections and low-lexical interjections was established. High-lexical interjections convey emotions by lexical as well as prosodic factors, while low-lexical interjections convey emotions mainly by

prosody. In another experiment stimuli spoken with congruent or incongruent prosody were compared with each other. Again the question was ‘Which emotion was expressed?’ and the listeners had to assign one of the four emotional categories happiness, anger, sadness, or disgust. In case of stimuli with incongruent prosody, correct identification of either the lexical or the prosodic meaning counted as a correct answer. Both high-lexical interjections and low-lexical interjections showed a higher percentage of correct judgements when spoken with congruent prosody compared with stimuli spoken with incongruent prosody. High-lexical items showed a stronger effect than low-lexical items, which the authors interpret as due to reduced lexicality of low-lexical interjection stimuli. Another analysis showed that prosodic cues yielded correct judgements more often than lexical information, and more so for low-lexical interjections. Metcalfe et al. (2009) performed perceptual ratings experiments, and they also found that listeners classify English interjections into interjections with high or low lexical information. Participants listened to the interjection stimuli and categorized them as positive or negative, by pressing either of two keys. (Thus, it was not a lexical decision experiment.) The results were that responses to ambiguous interjections (low-lexical interjection) took slightly longer than for unambiguous utterances (high-lexical interjections). However, the reaction times for utterances spoken with neutral list intonation were even longer. Neutral list intonation could be compared with a mismatching condition. The general question of whether semantic complexity is reflected in processing time has been affirmed by, for example, Gennari and Poeppel (2003) in a study on verb meanings. Lupker (2007) reviews the issue of processing of ambiguous words. Many studies have found an ambiguity advantage in lexical decision experiments on written stimuli (e.g., Forster and Bednall 1976; Gernsbacher 1984), while later studies have found an ambiguity disadvantage in lexical decision experiments with spoken stimuli (Rodd et al. 2002). Klein and Murphy (2001, 2002) suggest, from priming experiments, that different senses of a word are represented more distinctly in memory than word forms such as orthography or phonology.

Corpus analyses of Swedish prosodic emotional expressions in relation to lexical meaning (Abelin 2010) suggested that the lexical meaning of some interjections (i.e., the low-lexical interjections) could not be determined without prosody; many ambiguities exist in written form (without prosody), but not in the spoken form(s). These studies converge in the possibility that emotional prosody is integrated in lexical processing. Studies on ambiguity show that there could be different processing times for high-lexical and low-lexical words. Several studies show that emotional prosody affects word processing. If low-lexical interjections are affected more by mis-matching prosody, in the present study, this could show that emotional prosody has a position within the lexicon.

The Swedish Low-Lexical and High-Lexical Interjections of the Study

Typical low-lexical interjections are the following. The grapheme string is given followed by the appropriate, disambiguating prosodies.

ah: anger, happiness, disgust

åh: happiness, sadness

äh: anger, disgust

öh: disgust

These are then eight different low-lexical interjections. To repeat, the meaning of low-lexical interjections can't be determined without hearing the prosody; the phoneme string is not sufficient. However, it must be added that low-lexical interjections are quite dependent on context, in a wide sense, for their interpretation. Examples of high-lexical interjections are the following: *hurra* (yippee), *usch* (yuk), *tjoho* (yippee), and *ack* (sadness).

The words that were counted as low-lexical interjections were, on the basis of ambiguity, partly confirmed by lexicon definitions (Nationalencyklopedins ordbok – The dictionary of the Swedish Academy 1995), partly in comparison with the emotional recognition rates of similar words in German (Dietrich et al. 2006), and partly by a survey with Swedish native speakers:

In order to check the emotional content of the interjections without prosody a questionnaire was distributed to an independent group of 43 beginning students of linguistics. They were instructed to assess one of five emotions (happy, angry, sad, fearful or disgusted) to 19 interjections in written form. The result is shown in Figure 1 and gives a possible measure of high and low lexicality. The interjections to the left are unanimously given one emotional label by the 43 subjects, that is, they are high-lexical interjections; the subjects are sure of their emotional content. The interjections to the right are given several emotional labels, that is, they are low-lexical interjections, and more ambiguous. The low-lexical interjections, according to the definition above, *ah*, *åh*, *öh* and *öhh* are the most ambiguous. However, the result of the questionnaire shows that *åh* could be counted as a high-lexical interjection, while *äsch* could be counted as a low-lexical interjection. In spite of this, *ah*, *åh*, *öh* and *öhh* are counted as low-lexical interjections on the grounds that they convey emotions mainly by prosody.

Figure 1. Number of subjects who assigned the same emotion to a certain interjection. The interjections to the right where given several emotional meanings and the number represents the majority vote by the judges.

It is still an open question whether emotions are best described as categories or as emotional dimensions. This study examines emotional categories.

3. MATERIAL AND METHOD

The method consisted of lexical decision experiments where reaction times to different spoken interjections (high-lexical interjections and low-lexical interjections) were measured. The interjections used were recorded with matching or mismatching prosody. Examples are high-lexical interjections *hurra* (yippee) with happy prosody (match) and with sad prosody (mismatch), and low-lexical interjections *äh* (bah) with angry prosody (match) and with sad prosody (mismatch). Furthermore the word stimuli were analysed acoustically and compared with reaction times. Swedish interjections were recorded by a 22-year-old female drama student having Swedish as her mother tongue (Gothenburg dialect). The recordings were made in both matching and mismatching prosody. Non-word interjections were also recorded with differing emotional prosody. The success of the expressions was checked with two other actors. The following contexts for elicitation of the interjections were given to the speaker (modelled on the study by Dietrich et al. 2006):

- a) *Happiness*: the speaker has just won a lot of money from betting on horses;
- b) *Anger*: the speaker is furious with a person she doesn't like, because that person has behaved badly and is not a bit remorseful;
- c) *Disgust*: the speaker is looking at worms crawling around in an open wound;
- d) *Sadness*: the speaker has just heard that a close friend is seriously ill;
- e) *Fear*: the speaker enters a dark abandoned house in the middle of the forest.

Two experiments were run, experiments A and B. The reasons for having two experiments were to not have too many stimuli in one experiment, and to test separately a larger number of words of only two emotional groups (experiment B).

The Test Stimuli

The test stimuli of experiment A that were analysed are shown in Table 1.

Table 1. The analysed test stimuli of experiment A. Words in Swedish, with emotional prosody within parentheses

Low lexical		High lexical	
match	mismatch	match	mismatch
ah (angry)	ah (sad)	asch (angry)	asch (fearful)
äh (happy)	äh (fearful)	nej (angry)	nej (fearful)
äh (sad)		nä (angry)	nä (fearful)
äh (angry)	äh (sad)	äsch (angry)	äsch (fearful)
		hurra (happy)	hurra (angry)
		ja (happy)	ja (sad)
		jippi (happy)	jippi (sad)

Low lexical		High lexical	
match	mismatch	match	mismatch
		tjoho (happy)	tjoho (sad)
		yes (happy)	yes (sad)
		hjälp (fearful)	hjälp (angry)
		ack (sad)	ack (disgusted)
		håhåjaja (sad)	håhåjaja (disgusted)
		ojoj (sad)	ojoj (disgusted)

In total there were 60 stimuli in experiment A, 33 real words and 27 non-words. The 33 real words were the test words analysed, that is, the words that had matching and mismatching prosody (see Table 1). In experiment A five emotions were tested: angry, happy, sad, fearful and disgusted.

The test stimuli of experiment B are shown in Table 2.

Table 2. The test stimuli of experiment B. Words in Swedish, with emotional prosody within parentheses

Low lexical		High lexical	
match	mismatch	match	mismatch
ah (happy)	åh (disgust)	blä (disgust)	blä (happy)
åh (happy)	äh (happy)	fy (disgust)	fy (happy)
äh (disgust)	öh (happy)	hu (disgust)	hu (happy)
öh (disgust)		tvi (disgust)	tvi (happy)
ah (disgust)		urrk (disgust)	urrk (happy)
		usch (disgust)	usch (happy)

In total there were 60 stimuli in experiment B. Twenty of these were the test words analysed, that is, the words that had matching and mismatching prosody (see Table 2). There were 28 non-words, the same non-words as in experiment A. In experiment B only two emotions were tested: disgusted (in matching conditions) and happy (in mismatching conditions). (There were thus 12 words with other emotions that were not analysed.)

Testing Procedure

Perception of 33 Swedish interjections was studied in the lexical decision experiment A. The listener group of experiment A consisted of 22 speech therapy students, ages around 22 years, without any known hearing loss. Experiment B had the same design, but fewer emotions. Perception of 20 Swedish interjections was studied in the lexical decision experiment B. The listener group of experiment B consisted of 14 beginning students of linguistics, without any known hearing loss, ages around 20–35 years.

The subjects listened to spoken interjections presented over headphones. In both experiments A and B they had 1500 msec to respond, and 1500 msec pause between each of the stimuli. In the lexical decision experiments subjects were asked to decide, as quickly as possible, whether a given item was a real word or a non-word. The response was given by pressing one of two buttons, one for yes (real word) and one for no (non-word).

Recording Equipment and Software

The stimuli were recorded with a Sennheiser MZA 900 P (headset microphone) with the programme Logic Pro 9.0 and later cut in Praat 5.0. The software for the lexical decision tests utilized was the reaction time programme PsyScope X B57D.

Analysis

Comparison of reaction times was made between the same word with matching prosody and with mismatching prosody. The response times to the real words (the matching high-lexical interjections and low-lexical interjections and the mismatching high-lexical interjections and low-lexical interjections) were analysed; the non-words were there as a control.

Comparison was also made between groups, high-lexical interjections and low-lexical interjections, with matching and mismatching prosody. The reaction time analyses were compared with acoustic analyses of the stimuli of the experiments.

4. RESULTS

The results of the lexical decision experiments are presented first. Thereafter, the results of the acoustic analysis are presented, and finally, the reaction-time data and the acoustic analyses are related to each other. As there are, by necessity, differences in the number of high-lexical interjections and low-lexical interjections there will not only be quantitative data but also more qualitative presentations of data.

Results from the Lexical Decision Experiments

Experiment A

Figure 2. Experiment A. Stimuli with mismatch between lexical content and emotional prosody. HLI = high-lexical interjections; LLI = low-lexical interjections; MM = mismatch.

Stimuli with mismatch between lexical content and emotional prosody were recognized more slowly than matching stimuli, see Figure 2. Low-lexical interjections were recognized more quickly than high-lexical interjections in matching conditions, but low-lexical interjections were recognized more slowly than high-lexical interjections in mismatching conditions. The difference between matching high-lexical interjections and mismatching high-lexical interjections is significant, $t(4.2)$, $p = .0004$. The difference between matching low-lexical interjections and mismatching low-lexical interjections is significant, $t(6.5)$, $p < .0001$. Studying each low-lexical interjection item, the result is that mismatching prosody always slows down reaction times.

One conclusion of the results presented in Figure 2 is that mismatch gives longer reaction times, especially for low-lexical interjections. Another conclusion is that the interjections do get recognized, even though the prosody mismatches.

Experiment B

Only words for disgust and happiness were tested, in matching conditions or in mismatching conditions. In mismatching conditions disgust words were pronounced with happy prosody.

Figure 3. The figure shows that happy prosody speeds up recognition of disgust interjections in mismatch. The matching condition is disgust and the mismatching condition is happiness. (Cf. Figure 2 for Experiment A.).

In experiment B happy prosody speeds up recognition of disgust interjections in mismatch, and more so for high-lexical interjections than for low-lexical interjections. But as well as in experiment A, low-lexical interjections are slower than high-lexical interjections in mismatch.

Another way to put this is that mismatch affects low-lexical interjections more than it affects high-lexical interjections, and that low-lexical interjections are speeded up less by happy prosody than high-lexical interjections, indicating that recognition of low-lexical interjections is more sensitive to mismatching prosody. The low-lexical interjections are few, but the result is very pertinent, since the low-lexical interjections are in general shorter phonologically (only one vowel phoneme) than the high-lexical interjections. The result holds also for individual interjections, not only for means.

The longer reaction times of high-lexical interjections, as compared with low-lexical interjections, in the matching conditions could be an effect of complexity in processing, or a phonological (but not phonetic) length effect.

Summary of the Results of the Lexical Decision Experiments A and B

Mismatching interjections were generally not discarded as non-words. Therefore, it seems that mismatching prosody can affect the processing of an interjection, but it does not hinder an interjection from being recognized.

Figures 2 and 3 show that, in mismatching conditions, low-lexical interjections have longer reaction times than high-lexical interjections. High-lexical interjections have longer reaction times than low-lexical interjections when in matching conditions.

There is, however, a great difference between the results of experiments A and B: the relations between matching and mismatching conditions are opposite. In experiment A, mismatch leads to longer reaction times, while in experiment B, mismatch leads to shorter reaction times. This result led to the further acoustic analysis of the different emotional prosodies, in order to see whether the reaction times were also affected by specific prosodies, and not only by the conditions match and mismatch; in the case of experiment B, matching prosody always expresses disgust, while mismatching prosody expresses happiness. Could it be that happy prosody speeds up reaction times?

Figure 4 shows the mean reaction times for the five different emotional prosodies in matching and mismatching conditions. It seems that the different emotional prosodies have inherent processing times independent of whether the emotional prosodies match or mismatch the lexical content of the interjections. Mismatching happy (or active) prosody also speeds up recognition of both high-lexical interjections and low-lexical interjections. This is explored further in the acoustic analysis.

Figure 4. Means for reaction times in matching and mismatching conditions. Data from experiments A and B.

Acoustic Analysis

The questions for the acoustic analyses were the following: Are there systematic differences in F0 variation, or in durations, that correlate with the different reaction times that varied for different emotions? The variables that were analysed were F0 mean, F0 minimum, F0 maximum, difference between F0 maximum and minimum, and durations of the stimuli. The stimuli analysed are the ones used in both experiments A and B.

Comparison of the Durational Analysis of Stimuli with Results from the Reaction-Time Experiments

Durations of Stimuli in Matching Condition

Figure 5 shows that 'angry' prosody has the shortest durations and 'sad' prosody has the longest durations. The durations are compared with the reaction times for matching prosody. The durations of the stimuli expressed with 'angry', 'happy', 'sad' and 'disgusted' prosodies (in matching conditions) seem to co-vary with the corresponding reaction times.

There is thus a kind of length effect, but not a phonological one. It is an effect of different emotional prosodies, in relation to the recognition point of the words. It takes longer, in general, to pronounce a word with disgusted prosody, than to pronounce the same word with happy prosody. That is why, for example, a disgust word expressed with mismatching happy prosody is recognized quicker than the disgust word with matching prosody (seen clearly in experiment B). The different durations of different emotional prosodies is a factor which has to be controlled for in general, in reaction time experiments.

Durations of Stimuli in Mismatching Conditions

Are emotional prosodies expressed in the same way when the prosody is applied in a mismatching way? In other words, does mismatch in itself have an effect on the production of prosody, or do mismatching prosodies have the same characteristics as the corresponding matching prosodies? For example, does hurra with mismatching 'angry' prosody have the same acoustic characteristics as asch with 'angry' prosody?

Figure 5 shows that the relative durations of 'angry', 'happy', 'sad' and 'disgusted' prosody in mismatching conditions are similar to matching conditions, although not significantly correlated.

It can therefore be argued that the durational characteristics of prosodies when produced on mismatching words are not drastically changed. The durations also correlate with reaction times in mismatching conditions.

The result from experiment B that both high- and low-lexical interjections are recognized faster in mismatching conditions than in matching conditions was clearly due to durational characteristics of the different emotional prosodies 'happy' and 'disgusted'.

Figure 5 shows that there seem to be correlations between reaction times in the lexical decision experiments and the durations of stimuli, for the five emotions. The variables RT M and RT MM had a correlation of 0.93, $p = .005$. (Correlation between duration M and duration MM = 0.41, between RT M and duration M = 0.85, between RT MM and duration MM = 0.72 were not quite significant.)

Figure 5. Correlations between the reaction times and the durations of stimuli for five emotions, in experiments A and B. *Fearful' has only one matching word.

This does not mean that there is a trivial correlation between durations of stimuli and reaction times. When we separate the data into high-lexical interjections and low-lexical interjections, it is clear that reaction times also depend on whether the interjection is a high-lexical interjection or a low-lexical interjection and whether it occurs with matching or mismatching emotional prosody. Cf. Figures 2 and 6.

Figure 6. Durations of matching and mismatching high-lexical interjections and low-lexical interjections. Cf. reaction times in Figure 2.

Figure 6 shows that in no case do mismatching low-lexical interjections have longer durations. The longer reaction times of mismatching low-lexical interjections are thus due to longer processing times, because of the mismatching prosody.

Low-lexical interjections do not always have the shortest durations, so durations do not seem necessarily connected to low-lexical interjections; durations seem rather to be connected

to different emotional prosodies. The conclusion is that the low-lexical interjections are dependent on emotional prosody for normal processing and that they are more affected by mismatching prosody.

F0 variation

The F0 variation (minimum/maximum etc) was not correlated to the distinction high-lexical/low-lexical but to a certain emotion. In mismatching condition the variation for angry prosody is greater as compared with matching conditions. However, there is no general difference in F0 variation between matching or mismatching high-lexical interjections and matching or mismatching low-lexical interjections. This means that the differences in reaction times between matching and mismatching high-lexical interjections and matching and mismatching low-lexical interjections, shown in Figures 2 and 3, do not depend on F0 variation, but most probably on difficulties of processing mismatch as such.

5. DISCUSSION

Matching high-lexical interjections take longer than matching low-lexical interjections to process. This could be explained in different ways, for instance, that high-lexical interjections have more information to process than low-lexical interjections. An alternative explanation is that since the ambiguities of many low-lexical interjections do not give longer processing times, this could be an argument for prosody being connected to the lexical representation and that low-lexical interjections are in fact different morphemes.

The interpretation above is also compatible with low-lexical interjections having longer processing times than high-lexical interjections in mismatching conditions: low-lexical interjections are affected more than high-lexical interjections by mismatching prosody, since prosody is connected to the lexical representations in low-lexical interjections and normally disambiguates the ambiguous phoneme string (like *oh*). Longer reaction times are caused by a choice between two or more lexical units, where semantic and prosodic specifications do not fit with the prosodic input (e.g., the duration).

There could thus be specifications of prosody in the lexical representation, which however, does not inhibit the recognition of the word, when the prosody is mismatching. These specifications normally interact with prosodic information on a processing level higher than the lexical representation. With words like low-lexical interjections (which have more prosodic specifications than high-lexical interjections in the lexical representation), the listener requires a longer time to process whether the stimulus is a word or not, when the prosody is mismatching.

What different emotional prosodic specifications could there be, then, in the lexical representation of interjections (especially for low-lexical interjections) that are activated (or not) in the recognition process? These could be duration—shorter for anger, longer for disgust; F0 mean—higher for sadness, lower for disgust; F0 variation—small for anger, large for happiness; and others, for example, location of F0 peak, voice quality (all in combination with other acoustic-perceptual specifications, e.g., low F1, low F2, high F3 for [o]).

Are there correlations between durations and reaction times? The differing reaction times of different emotions show some correlation with durations for emotions, however, not for

low-lexical interjections in mismatching conditions. Therefore, the mismatch as such affects the processing. Furthermore, the fact that low-lexical interjections are processed more slowly than high-lexical interjections in mismatching conditions cannot be attributed to a phonological length effect; low-lexical interjections are shorter than high-lexical interjections phonologically (often only one vowel). The shortness of the low-lexical interjections and the nevertheless slower processing of low-lexical interjections in mismatching conditions is an argument for mismatching prosody being more detrimental for the low-lexical interjections. Since low-lexical interjections are ambiguous, they are more dependent on matching prosody for their interpretation. High-lexical interjections are not as dependent on matching prosody for their recognition, and therefore do not get as long reaction times from mismatching prosody as low-lexical interjections do.

As mentioned above, interjections with mismatching prosody, low-lexical interjections or high-lexical interjections, are usually not discarded as non-words. However, there is a higher rate of wrong responses to mismatching low-lexical interjections as compared with mismatching high-lexical interjections.

There was no correlation between F0 variations and reaction times. There are indeed differences in F0 variation between the different emotions, but these do not correlate with reaction times. There is, of course, a possibility that other acoustic parameters are involved. Voice quality and loudness, as well as, for example, onset of F0 rise could also play a role in the reaction times when processing interjections.

The results of the longer processing times of mismatching low-lexical interjections as compared with mismatching high-lexical interjections are compatible with the results of Metcalfe et al. (2009) on English interjections. They did reaction-time studies on categorizing non-ambiguous (high-lexical) interjections, ambiguous (low-lexical) interjections, and interjections spoken with list intonation, as positive or negative. Metcalfe et al. (2009) found that interjections spoken with list intonation, that is, mismatching intonation, were reacted to more slowly than both the high-lexical interjections and low-lexical interjections with appropriate prosody.

Dietrich et al. (2006) in the study of recognition rates for German interjections with matching and mismatching prosody found that high-lexical items showed a stronger effect than low-lexical interjections, that is, correct recognition of high-lexical items was diminished more than for low-lexical interjections, in mismatching conditions. This result is not in accordance with the present results from the lexical decision experiments, where low-lexical interjections were affected more in mismatching conditions, than high-lexical interjections were. However, Dietrich et al. (2006) also found that prosodic cues yielded correct judgments more often than lexical information, and more so for low-lexical interjections.

In accordance with Nygaard and Lundervald (2002), Dietrich et al. (2006), Nygaard and Queen (2008), Metcalfe et al. (2009) and Wurm (2012) there is evidence that emotion-congruent prosody facilitates processing of emotional words and gives the best recognition. It could be added that 'integration' is the normal state and that separation hinders recognition.

What is the interjectional lexical unit in traditional terms? *Åh* (happy) and *åh* (sad) could be seen as different morphemes. They are not homonymous, or polysemous, since they have different meanings and (partly) different forms. They are thus as separated as *å* [o] 'river' and *åh* [o] 'happy emotion'? This could be tested in priming experiments. Another viewpoint is that interjections could also be seen as independent phrases/utterances. Interjections are words in the lexicon, which function as independent phrases.

In light of the results it is plausible that emotional prosody is specified in the lexicon. This allows both for specification of emotional prosody at the lexical level at the same time as it is compatible with emotional prosody being universal. It is related to bodily and mental reactions and thus indexical. E. g. Abelin (2008), Pell et al. (2011) have shown that the interpretation of emotional prosody is also related to non-verbal communication.

How is emotional prosody in the representation of the lexical unit compatible with general emotional prosody (which is quite universal, and which also works in communication with small children and animals)? The preliminary answer goes as follows: It is part of the semantics of interjections to express emotions. Speakers express emotions indexically in interjections. The listeners experience these interjections with emotional prosody, beginning in childhood. Emotional prosody of interjections thus becomes coded in interjections through listeners' experiences; the emotional specification of lexical units is learned from experience. Therefore, there are indexical elements in the lexical representations of interjections. Over the years, interjections that were originally quite unarticulated (wild forms) have become more and more conventionalized, both ontogenetically and phylogenetically.

CONCLUSION

Stimuli with mismatch between lexical content and emotional prosody were recognized more slowly than matching stimuli, especially for low-lexical interjections. This means that the mismatch between lexical content and emotional prosody affects the recognition process for this type of word. A possible explanation for this is that prosody is more specified in the lexical representation of low-lexical interjections, as compared with high-lexical interjections.

The results thus show that interjections can have a certain degree of emotional-prosodic specification in the lexical representation and that emotional prosody is part of the phonological representation of the interjections. Emotional prosody is thus part of the linguistic system. At the same time this implies that the lexicon is not separated from other cognitive and communicative abilities, such as understanding and expression of emotional prosody in general. Interjections are special words for communicating the here and now and they show the connection between lexicon and general emotional prosody.

The results are also compatible with that low-lexical interjections form different lexical units for different emotional meanings. Allowing for emotional prosody in the phonological specification of the lexicon, words are not ambiguous but represent different morphemes.

It is left to further research to find out whether other lexical categories, such as emotional adjectives or evaluative sound symbolic nouns, e.g., pejoratives, also carry emotional prosodic specifications.

CREATIVE COGNITION: A ‘WAVE METHOD’ ANALYSIS OF FRANZ KAFKA’S ‘METAMORPHOSIS’

Matthias Krug

University Complutense of Madrid, Spain

ABSTRACT

‘Metamorphosis’ by Franz Kafka is analyzed in this paper from a cognitive literary perspective, mindful of recent advances in the field of creative cognition (including Forceville: 2009). Employing the ‘Wave Method of Cognitive Literature Analysis’ (previously employed in linguistic contexts by Bailey: 1973), a procedural method developed by the writer of this paper, this paper displays the importance of social context and agents in the process of transforming fiction from first cognitive impulses of the writer to the final linguistic end product. Calling for a cognitive incorporation of the reader in the analytical process, in what is referred to here as the ‘writer-reader dynamic’, various linguistic aspects with a solid foundation in linguistic paradigms such as Blending Theory (Fauconnier and Turner 2003) are examined for their impact on the creative spaces of the prototype reader. In doing so, this analysis finds that the ‘container’ image schema of Gregor Samsa’s transformed body is of particular relevance, whilst the extended ‘insect’ metaphor is found to have varying mental activations depending on agents involved. The assumption of Stockwell (2009) that an interaction takes place between texts and humans in the reading of literature is thus built upon in this paper.

Keywords: Kafka, metamorphosis, metaphor, wave method, image schema, container, agents, writer, publisher, translator

1. INTRODUCTION: THE WRITER-READER DYNAMIC

One of the most unique, daring and diversely interpreted writers of the 20th Century, Franz Kafka (1883 – 1924), of Czech nationality, but a writer in the German language, shall be analyzed here on hand of a cognitive literature analysis model developed by the author of this paper. The ‘Wave Method for Cognitive Literature analysis’, formed with a firm basis in linguistic theory and on hand of the writer’s own literary publications and experiences, will

be discussed in the methodology section which follows (2.0). Prague-born Kafka published relatively little during his lifetime (Fechter, 1952: 489), which will be an observation of some importance in the analysis of the cognitive intentions of the author, taking into account the worldly input as Kafka struggled to realize his writing ambitions against the pressure of everyday necessities in the workplace. Kafka's lifetime saw only a select few titles published, amongst them the short story 'Metamorphosis' which is to be examined here, whilst the majority of his work was published posthumously.

'*Die Verwandlung*' in the German original, created and written in November and December 1912, would indeed become one of his most lasting works. Countless volumes have been written in attempting an all-encompassing analysis of both Kafka's work in general (such as Mueller 2009), as well as 'Metamorphosis' specific work (including Beicken 2007), and finally work with an altogether different orientation like the Jewish-orientated analysis of Groetzinger (1992: 7), who writes:

"Schliesslich hat sich die Rezeption dieses Erzählwerkes für eine Vielzahl von Deutungen als geeignet erwiesen, die allesamt ohne die jüdische Komponente auskommen konnten."¹

It is precisely this breadth of interpretations which makes this work so fascinating for the 'Wave Method' cognitive analysis, which takes into account what each different reader brings to the reading. Thus, for example, a Jewish reader will interpret Kafka's 'Metamorphosis' in one way, perhaps similar to the way that Groetzinger analyzed the texts, while a reader without any knowledge of the Jewish religion may bring an entirely different world view to the reading. Which interpretation, then, is correct? The answer which is developed in the here gained results would seem to indicate that each is correct in the context of its own entirely specific writer-reader dynamic.

2. PROCEDURE: THE WAVE METHOD OF COGNITIVE LITERATURE ANALYSIS

The here following analytical model is the result of a lengthy period of investigation into the cognitive mechanisms and procedures of creative writing. This has been aided and amplified by my own experiences as a published fiction writer in the novel and short story form. What is proposed here is a linear analysis method, which begins by analyzing the cognitive impact of the title upon the reader, and the there following entire reading experience in the order of receptivity of a text; from beginning to progression to conclusion, considering all the while the central plot-related questions. The analysis then takes the linguistic end product as the basis for the receptive impulses, and deduces cognitive choices of the writer at the various productive stages of the writing process. Finally, taking into account the 'worldly input' of the writer at the centre of the creativity process, as shall become evident in Figure 1 to follow, the cognitive intentions of the writer in producing the particular piece of writing will become evident. A 'Wave theory' approach has been utilized previously in linguistic studies, specifically in the field of sociolinguistics. The concept of a 'Wave theory' was

¹ Translation: "For the reception of this body of work has been suitable for a wide variety of interpretations, all of which were able to function without the Jewish component."

employed by Bailey (1973), for example, to explain lexico-grammatical changes in varieties of American English, thus identifying aspects which Chomskian theory did or could not deal with due to the latter's omission of social explanations. This analysis method which follows here attempts to facilitate a thorough cognitive analysis of both the writer and reader's mental processes through the basis of a linguistic analysis of the text. The intention then is to include both productive and receptive aspects of literature in the analysis, for as Fairclough (1995: 9) pointed out: "the principle that textual analysis should be combined with analysis of practices of production and consumption has not been adequately operationalized...". Thus, this analysis method aims to clearly showcase and analyze all aspects of textual production and consumption in the realm of creative fiction writing. The intention behind such a procedural analysis is to demonstrate that while traditional literary analysis lays a keen emphasis on the intentions of the author in the linguistic choices, the current analysis method will attempt an all-encompassing analytical approach, which will crucially also incorporate the reader as a key cognitive actor in the creative writing process. This broader approach to literary analysis is not just useful when taking into account the recipient of the work of literature, who will in this case be the prototype reader that is the author of this study, but can also thereby lead to valuable insights into the writer's cognitive intentions. In his afterword to the German edition of Franz Kafka's 'Metamorphosis' (2009: 71), Egon Schwarz writes, when talking about the literary theories of reception theory and reception aesthetic which have come into focus in recent years:

"Wir deuten nicht so sehr Kafkas Fiktion, sondern unsere eigenen Empfindungen bei ihrer Lektüre oder, genauer: die Begegnung der beiden im historischen Augenblick unserer Gegenwart."²

This notion also captures the essential promise of the 'Wave Method for cognitive literature analysis'³, for it not only offers to bring together the two focal points of writer and reader into the present moment which Schwarz mentions, but offers the possibility for the reader to do so from the inherently solid standpoint of their own receptive capabilities. Here follows the procedural model of analysis to be employed and thereafter the explanation of the various stages identified, as well as how they will be analyzed:

Figure 1. Wave Method of Cognitive Literature Analysis.

² That is (my translation always from here onwards): "we interpret not so much Kafka's fiction, but our own sentiments upon reading it, or, more precisely yet: the encounter of the two in the historic moment of our present."

³ Referred to hereafter simply as the 'Wave Method'.

Table 1. Key for analysis method

Wave	Content	Analysis to be employed
1	Writer's worldly input	Research of key worldly and contextual input
2	Writer's writing stage	Analysis of cognitive intentions of the author
3	Writer's editing stage	Analysis of stylistic resonance of text
4	Publisher's editing stage	Interview with publishers and indicators from research
5	Linguistic end product (in the form of novel or short story, etc.)	Textual linguistic analysis
6	Reader reception	Cognitive analysis of receptive impact

3. RESULTS

3.1. The Title

The very first cognitive reference for the reader is the title. Incidentally, it is normally this very title which the author places, as deftly or aggressively as necessary, as the final, provocative or incisive touch. From own experience, and also from other writers' interviews and recollections⁴, the title is usually finalized from a number of possible drafts after having written the entire story, making for an even more important impact of the title. This is the essence of the work of fiction, the few words which must contain the soul of the piece and attract the reader's attention, rather immediately. In cognitive terms, this is a case of working against what Stockwell (2009: 7) calls 'prototypicality', that is it must be sufficiently different from all the other offerings in the bookshop to stand a chance of being picked up by the reader⁵.

On then to Kafka's own reversal of prototypicality through his choice of the title, which is achieved instantly by asking the reader to create a new reality on hand of the information that is being insinuated in the title. The one-word title in English centers the entirety of reader attention upon the central focus of the story ahead, from the very beginning. The reader is asked to focus entirely on a metamorphosis.

And from the very start we, as the reader, take into account that some kind of change is going to take place in our established world view. We must not wait long to find out, on hand of the linguistic end product that is the text, what that change will be (as the following subsection will demonstrate).

The author has then succeeded, already, through the word choice of the title, in focusing the reader's attention directly on the subject matter at hand; that is the bodily transformation through which he will place his social critique in the reader's mind.

⁴ See for example Ernest Hemingway, in the Paris Review: Issue 18, Spring 1958.

⁵ Thus, for example, my first published short story (Bartleby Snopes Literary Magazine, USA, July 2009) was entitled 'Other side of the moon', with the first word of the title already suggesting and implying difference, and essentially aiming for a heightened cognitive impact upon the reader.

3.2. The Beginning

The beginning of the story is highly relevant in the ‘receptive’ phase of the ‘Wave Method’ analysis, since the change insinuated by Kafka’s title (‘Metamorphosis’) immediately materializes within the very first sentence. Thus, in that highly cognitive opening sentence Kafka wrote (2007: 87): “When Gregor Samsa awoke one morning from troubled dreams, he found himself changed into a monstrous cockroach in his bed.” Here the receptive reading impact is immediately heightened with regards to the metamorphosis or change already signalled by the title and discussed above. That unknown change has now taken on the specific form of the ‘monstrous cockroach’ into which the main character has found himself transformed after waking up from troubled dreams, and the reader must now deal with this new reality.

In receptive cognitive terms this is achieved through the reader’s blend of ‘creative spaces’, as this study shall refer to the concept employed here to analyze the creation of a new fictional reality, employing a term adapted from the ‘mental spaces’ which Fauconnier and Turner (2003) discuss and which have been introduced in the Literary Review (section 3) above. The reference to creativity in this name showcases the belief of this study that cognitive creativity is indeed apparent on both sides of the writer-reader dynamic. As shall become evident, many of the creative spaces of writer and reader are also shared, or have similar inputs, such as the own bodily experiences. Here, the creative spaces of the prototype reader’s own general worldly experiences negating the possibility of such a metamorphosis, and specific memories of waking up from troubled dreams in a seemingly altered state take on a great importance in the blend, as can be seen in table 4 below. The input of creative spaces is initiated by the reading of Kafka’s opening sentence in which a human being has just been transformed into an insect. This cognitive activation of the opening sentence in the reader’s mind can be seen in table 4 below, which also portrays the possible (deduced) creative spaces of the writer in the dynamic transfer of fiction.

When, as discussed earlier in the Literary Review, Fauconnier and Turner point to such possibilities as “implicit counterfactual spaces” (2003: 87), this is now what is being shown in Table 2 below, for there is the input of creative space 2 in which a counterfactual action is being described: the metamorphosis of a human being (creative space 1) into an insect. For the prototype reader, this is essentially a counterfactual literary blend, for there is no known human case where a man has effectively been transformed into a real cockroach. At least for this reader, with cultural knowledge which negates the existence of magic, there is no known such case. And so it is at first a negation (in creative space 2) of the fictional blend proposed by the writer which takes place in the reader’s mind. Then other factors come into play. For one, the creative space 3 in which a specific bodily memory of waking up in a seemingly altered, or otherworldly state from a troubled sleep fits perfectly with the writer’s fitting description of these happenings in the fictional story. The writer’s skilfulness is now a real feature in the success of the creative blend in the reader’s mind. The blend is taking on shape now in the generic space, because a shared experience is leading to the shared information that both Gregor Samsa as a human being and as an insect are essentially *alive*. Finally, in the blend which then ensues within split-seconds of the reading of the linguistic end product of the entirely unusual metamorphosis occurring in a piece of fictional writing, the reader also implicitly employs his knowledge of the procedural schemas (Hogan 2003: 47) of reading.

Table 2. The transformation of Gregor Samsa

Actor	Creative Space 1	Creative Space 2	Creative Space 3	Generic Space	Emergent structure
Reader (receptive)	Identity: Gregor Samsa as human being.	Identity: Gregor Samsa as insect. (Counterfactual) Triggers reader's own general worldly experiences, which negate possibility of such a metamorphosis.	Identity: Reader's own bodily input of specific memories of waking up from troubled dreams with a seemingly altered state of being.	Identity: Gregor Samsa as living creature.	New received fictional reality: Gregor Samsa has been transformed in opening sentence into insect. Augmented by reader's knowledge of procedural schemas of reading.
Writer (creative)	Identity: Gregor Samsa as human being.	Identity: Gregor Samsa as insect. (Counterfactual) Example of heightened writing creativity in that it provides variation from standard and dissolves 'threshold of rationality'.	Identity: Writer's own bodily experiences of feeling suppressed and degraded in family surroundings.	Identity: Gregor Samsa as living creature.	New created fictional reality: Gregor Samsa has been transformed in opening sentence into insect. Forms the basis for the progression of the fiction writing process.

Note: Table showing dynamic transfer of fiction in Kafka's 'Metamorphosis', employing deduced writer creative spaces and prototype reader creative spaces.

Here, the reader is aware of the possible suppression of reality in fiction writing which indeed forms a tradition in literary writing. The literary device of transformation of characters into animals has been used extensively to bring across meaning and social critique in "literary traditions in which metamorphosis has been a regular choice of motive: fables, mythical tales, fantasy writings and meaningful parables." (Mueller: 2009: 43). Thus certain readers, including this prototype reader, are already aware of the historical tradition of such a change of a main character into an animal, although the timing of the metamorphosis right at the start is a fine plot-based choice on the part of the author to heighten readability.

Other readers who may not bring this awareness to the reading, or who are only subconsciously aware of this literary tradition, may rely more heavily on the procedural schemas of reading a work of fiction; that is to expect a problem to arise at the beginning, for this to be heightened in the middle of the story, and finally to be solved towards the end or the conclusion. The acceptance of the metamorphosis of Gregor Samsa would be based in this case more strongly on the procedural schemas than on specific knowledge related to literary traditions. In this specific case, the prototype reader's knowledge of this long-standing literary tradition and liking for fantastic fiction leads to the acceptance of the metamorphosis and successful activation of the blend of Samsa's transformation.

In terms of linguistic choices, the transformation of Gregor Samsa can indeed be seen as an extended metaphor placed right at the beginning of the story, and then systematically extended towards the solving of two central questions in the reader's mind:

- 1) will Gregor Samsa return to being a human once more? and
- 2) why has he been transformed into this beastly cockroach in the first place?

At this stage, even before moving on to the author's choice of metaphor and the choice of animal in particular, we should briefly consider wave 4 of the analysis method, which is the publisher's editing stage. In this case there is evidence of the role of the publisher in the creative writing process. Many of Kafka's works which were published posthumously indeed only appeared because his close friend and fellow writer Max Brod acted as any serious publisher would have done and ignored Kafka's last wishes to have all his works destroyed. Brod had them published. But this applies to other works, including 'The Castle'. In the case of 'Metamorphosis', which was published in Kafka's lifetime, there is an altogether different input at the publisher's editing stage (wave 4). Certainly in the English edition of the text examined in this study (Kafka: 2007), the original German 'ungeheueren Ungeziefer' (Schwarz, 2001: 5) has been *specified* in the English translation, which reads: "a monstrous cockroach" (Kafka, 2007: 87).

The specification of the insect in question therefore actively changes the reader experience in the two different languages. Thus, there is a difference here in terms of word choice in the translation, and one which has a very real impact upon the linguistic end product (wave 5). We are confronted with a specific insect in the English text analyzed, allowing for the reader to activate associated (cognitive activation of creative spaces for: cockroach) feelings of disgust and aversion from the very start, while the German original by Kafka offers more scope for the reader's imagination to create a detailed picture of the insect into which Gregor Samsa has so shockingly found himself transformed. What may seem at first glance a translator's issue indeed falls under the publisher's editing stage (wave 4) of the analysis method, for the publisher is ultimately the commissioner and finally responsible in terms of commissioning and approving the translation.

As has become evident in table 4 above, the beginning of the story is an example of heightened creativity on the writer's part, in that the second creative space contains information which is counterfactual to the writer's general worldly knowledge that the transformation of a man to an insect is quite impossible. This 'threshold of rationality', as I refer to it here, is then dissolved by Kafka's creative input, which is the new idea of transforming a man into a cockroach in order to lend additional emphasis to his social critique. It may be deduced from the reader's receptive reaction and the writer's worldly surroundings of a troubled familiar relationship⁶ that Kafka's own bodily experiences of feeling suppressed and degraded in his family surroundings also contributed to this creative blend. This then flows into the descriptive element of the first sentence, giving the sentence *authenticity* despite the seemingly fantastical happening which has just occurred. In terms of Hogan's (2003) mental activation pattern, the choice of the animal by Kafka in the creation process is an interesting one to consider. In a hypothetical writer mental activation pattern, the cognitive impulses of creativity might be represented as follows in table 3.

⁶ To be discussed shortly.

**Table 3. Hypothetical mental activation pattern of writer: creative activation
(Adapted from Hogan: 2003)**

Input node	Output node	Activation strength
Gregor Samsa + Family Situation + Financial Situation	Dog	+0.9
Gregor Samsa + Family Situation + Financial Situation	Cat	+ 0.8
Gregor Samsa + Family Situation + Financial Situation	Beetle	+ 0.75

Thus in this hypothetical creative activation pattern for Kafka, the outright 1.0 threshold for activation is not reached because there are various other options which are considered. The writer's worldly input may initially give more activation strength to the animals of 'dog' and 'cat', which are generally associated with living in conjunction with a family. An insect does not fit into this normal associative schema. Thus the hypothetical lower activation strength indicated above in table 3. But the choice of an insect in the story may then be linked to Kafka's need for an animal of less prestige and usefulness than a dog or a cat. This is a notion which cannot be confirmed with real data, but table 3 hints at the extent to which creativity relies on variations from the standard or prototypical solution. Thus it displays Kafka's creativity in opting for the less common extended metaphor which essentially provides the optimal conveyer of the writer's cognitive intentions.

The cognitive messages of family depreciation which Kafka is trying to convey to the reader is thus in entire harmony with the choice of extended metaphor at the writer's writing stage (wave 2). An insect is useless to the family, just as Gregor Samsa becomes a useless, horribly grotesque nuisance to his family from the moment when he does not earn the family's wages any longer. Having thus initiated the receptive mental activation of the story, it is thereafter the wish of the reader to find out what happens to the man turned insect. In the context of successful fiction the progression (to be discussed here in the next section) of the story usually brings an intensification of the main character's dilemma, which is also the case with Gregor Samsa.

The reader is quickly informed that (Kafka, 2007: 87): "It was no dream." A possible standard solution to the creative variation chosen by Kafka (that Samsa is indeed only trapped in a nightmarish dream, as so many potential readers have been) is thus quickly extinguished. The counter-factual blend continues for the reader. And as the story progresses, it is indeed intensified. In highly descriptive detail, the reader now receives information relating to the actual feelings of Gregor Samsa within the confines of this new, monstrous body of his. Here the analysis of Kafka's use of image schemas is of particular interest. As we shall see in the here following section on the progression of the story, these entirely basic building blocks of our cognitive system again serve to enhance reader identification with the dilemma of Gregor Samsa.

3.3. The Progression: Examining the Impact and Use of the 'Container' Image Schema

Specifically of keen interest in the progression of the story is what Turner (1996: 16) identified as the 'container' image schema, which is part of shared human experiences of our

bodies and includes an interior, exterior, and a boundary that separates them. Crucially, there is no cross-cultural difference in this regard, because each human being can relate to this bodily experience, making perhaps thereby for part of the universal appeal of Kafka's story. This can be linked to the following theory: "Embodiment or 'grounding' hypothesis – (which) contends that language partly makes sense because it is tied to our bodily being in the world" (In Brone and Vandaele, Eds, 2009: 12). This focus on bodily feelings effectively negates any differences which might be brought about by cross-cultural differences. Whilst the aforementioned translation (at wave 4) means a different reading experience for German or English readers, for example, the writer's concerted use of the 'container' image schema means there is conformity across cultures in terms of allowing the reader to actually feel the troubling bodily experiences of Gregor Samsa.

The 'container' is used on multiple occasions. Firstly the body of the cockroach which is described in exquisite detail from the point of view of Gregor Samsa from the second sentence onwards (Kafka, 2007: 87): "His numerous legs, pathetically frail by contrast to the rest of him, waved feebly before his eyes." Here, the change becomes starkly felt for the reader, who is seeing the fictional world through the eyes of the transformed main character. There are thus various containers being activated here in the reader's mind; the container of Gregor's body, that of his head, through which we have the vision of the world which he now has, disgusting feeble legs included, and finally the container of the room within which he finds himself trapped. If that were all not enough, there is also the final container of the flat to contend with. It is this family flat in which his entire family lives and will constrict his activities as a cockroach to the point of suffocating Gregor's will to live. All are obnoxious containers that Samsa wants to escape from, mostly without success.

While he does escape from his room as the story progresses, he is quickly forced back inside by the disgusted reactions of his family. And escaping from the flat itself, which to this prototype reader seemed like the most interesting test available for the transformed insect (imagining the hilarity and drama of a scene where Gregor Samsa turns up at his hated office and confronts his detested boss), is in itself a utopia. The reader's entire receptive experience is centered variously in Gregor Samsa's mind, head, body or room. At rare intervals the container that is the flat at large is accessed. But the outside world is an inaccessible area in the receptive experience. Thus what becomes evident in the receptive progression of the story is the impossibility of escape from the container that is the body. In doing so, the writer has not only focused the reader's attention on Gregor's internal dilemma, but also multiplied the shocking effect of his metamorphosis at the beginning of the story.

Through this hideous body's only possible outlet – the eyes – the reader is shown around the room for the first time and later around the flat. Parallel to this development, the window which is mentioned early in the story and reappears again at intermittent intervals later, and offers some of the only glimpses of the misery that supposedly awaits outside the container that is the Samsa family flat. In the first such instance (Kafka, 2007: 87) the "drab weather outside – raindrops could be heard plinking against the tin window-ledges – made him quite melancholy." The main character's mood is succinctly captured by this view outside of his window upon first becoming transformed into the beastly insect, a tendency reinforced a few pages later in the reader's cognitive system when Kafka writes (2007: 92) that "he leveled his gaze as sharply as possible at the window, but unfortunately there was little solace or encouragement to be drawn from the sight of the morning fog". The prototype reader is here made acutely aware of the increasing desperation which Gregor Samsa feels as he is stuck

inside the container of his now hideous body, looking out of the window in the hope of encouragement or solace from the outside world. This will never come. Samsa is left in an entirely confused state, a notion emphasized by the foggiess of the outside world. But the reader is still hopeful that such an outside force may still transform the container of Samsa's insect body back into the human form we are all familiar with, as Mueller (2009: 46) points out: "The reader, who observes the changed man with interest, immediately creates hypotheses, which he/she takes from their everyday knowledge, und which they can then verify or falsify as the story progresses".

The container image schema is thus omnipresent because it is the central focus of the metamorphosis, which in turn becomes both the narrator's and the reader's chief preoccupation. Through Samsa's metamorphosis into an insect, the reader is in due course shown the inhumane living conditions which Gregor Samsa encounters in his family and professional worlds. But without any real hope of ever escaping from these interlocking worlds which are constricting his own dreams and creativity, he is entirely focused at all times on the 'container' that is his body. In receptive terms, it becomes evident that the 'container' image schema is repeatedly taken up to bring across this lack of hope for the cornered insect as his family becomes increasingly hostile (Kafka, 2007: 100): "Now Gregor didn't even set foot in the room, but leaned against the inside of the fixed half of the door, so that only half his body could be seen, and the head with which he was peering across at the others cocked on its side a little." Direct linguistic end product (wave 5) mentions of the containers that are the room, as well as the body and the head of the cockroach showcase once again the powerful receptive impact of suppression and helplessness on Samsa's part; there seems to be no escape route possible, and he is afraid even to set a foot outside of his own room. He maintains half of his terrible body hidden in order not to cause further revulsion amongst his family members.

In terms of productive level choices, the aforementioned extract very much displays Kafka's intentions to centre the reader's focus on the inner feelings of the insect Gregor Samsa. The extended metaphor of the insect continues, of course, but it is in terms of word choice at the writer's writing stage (wave 2) that Kafka so effectively and successfully creates the mood and resonance of this story. By choosing three universal 'containers' – room, body and head, Kafka creates an almost claustrophobic centricity on the inner feelings of his main character. In terms of Kafka's cognitive intentions in writing with this emphasis on the 'container' image schema, this allows the interpretation that the writer intended to highlight the family-related repercussions of the monetary obligations brought about by an exploitative, capitalistic system, where one family member often bore the burden of working to support the entire family. This notion is confirmed once more by Kafka's (wave 2 and 3) word choice in the immediate aftermath of the family's discovery of his altered condition, with the chief clerk also present and seeing that Samsa is no longer in a position to come to work in such a state.

In the receptive intake, this is undoubtedly a moment of temporary triumph for the main character with whom the reader now feels a bodily identification. Gregor has emerged from the prison-like 'container' of his room and still harbors the illusion that his family will morally support him in his quest to return to his former human condition. Going to his dreaded work as a travelling salesman – apparently selling cloths of different types – is fast becoming a utopia, as the chief clerk can now see. For the prototype reader, this is a moment of triumph in the inner battle which the insect Gregor is facing.

This sense of hopefulness at an eventual resolution of the problem is reflected here in Kafka's choice of words (wave 2 and 3) as Samsa looks out of the (container) flat once more through the window and hope mingles with the usual dreariness of family and workplace (Kafka, 2007: 100): "It was much brighter now; a little section of the endless grey-black frontage of the building opposite – it was a hospital – could clearly be seen, with its rhythmically recurring windows; it was still raining, but now only in single large drops, individually fashioned and flung to the ground." What delightful contrasts Kafka brings page-wards here from his creative mental impulses; the brighter view has now cleared away the earlier mist of his main character's hopelessness; the endless monotony of the building opposite to the flat, which is symbolic of the daily routine of a work he does not enjoy and the "rhythmically recurring windows"⁷.

So the reader is confronted with windows again, those eyes to the outside world which has now become so elusive to Gregor in his insect state. And consider at this stage Kafka's word choice of describing the continuing rain, symbolic of the continuing difficulty of the situation – as "single large drops, individually fashioned and flung to the ground." The writer's timing in producing this statement is highly significant in the writer-reader dynamic. Gregor Samsa's individuality is immediately reinforced through the single raindrops the moment after it becomes clear that he cannot go to work in the form of an insect, for he would indeed repel each and every costumer. But in this individual's newfound hope there is equally despair, and the reader is subjected to a cognitive hint of the fatal ending. The single rain drops are flung to the ground, rather than simply falling, or dropping, which would indeed have been the more standard word choices in cognitive terms for the writer. In applying a variation from the prototype here, the writer actively challenges the reader to imagine a possible ending to the story. A certain forcefulness is insinuated here by the author, which can be seen to draw from Kafka's personal experiences (at wave 1), which included coming to terms with the difficulty of following individual dreams in a system which dictated a steady need for income for the family that writing would not bring about.

On the prototype reader of this study, this inner struggle of Gregor Samsa in 'Metamorphosis', emphasized by the 'container' image schema, indeed directly had the receptive impact which can be seen in table 4 below. Into the reader's interpretation of the story thus flows the newly acquired knowledge of Kafka's own struggles to follow his passion of writing whilst at the same time having to earn a living for his family. This interpretation is supported factually (at the writer's worldly input, wave 1), then, by the writer's own admission that he indeed (Beicken, 2007: 8):

"hated his job, because it hinders him at his writing. Complaints about his office were frequently found. In his letters to his fiancée Felice he wrote: 'the office is a horror...' 'Entirely incapable to deal with the office.' Consequently Gregor (Samsa) portrays the professional world as an entirely overwhelming human affair..."

This is an important observation from a receptive analytical point of view in that my own experiences and memories as a young writer needing to earn a living with other professions such as teaching or journalism undoubtedly flow into my understanding of Kafka's meaning. Similarly, a reader with a Jewish background, such as the one cited in the early stages of this

⁷ The poetically flowing alliterated English version here again brought about by the translator's input at wave 4.

Kafka analysis, might more readily interpret the Jewish aspects of the story, while a reader with family problems might place more emphasis on the lack of empathy displayed towards the transformed Gregor Samsa by his family as he struggles to become human again. Clearly, then, reader identity and past worldly experiences are crucial in the writer-reader dynamic, as can be seen from table 4 below.

Thus it may be deduced that Kafka's cognitive intentions in the writing process could have been to criticize the societal and professional inhumanity of his time and age – something which he found the perfectly fitting extended metaphor for in the insect that became Samsa. Added to this there was also undoubtedly a strong impetus in this story from his own frustrations as a writer having to make a living through other professions if he was to realize his ambition of liberating himself of the influence of his own family and authoritarian father and to begin his own married life with the fiancée he wrote letters to in such revealing detail.

The extended insect metaphor then merges in the progression of the story to provide a further measure of hope for the reader that a resolution of Gregor Samsa's dilemma could be in sight. Thus when the chief clerk runs out of the flat after seeing Gregor's hideous body, and Gregor attempts to chase after him down to the street to stop him from making his job redundant, that altered body becomes active for the first time and takes our main character to the swell of the flat's door.

Table 4. Use and effect of 'container' image schema in Kafka's 'Metamorphosis'

Actor	Linguistic device	Receptive effect	Productive choice	Cognitive intention	Worldly input
Reader (receptive)	'Container' Image schema.	Focus attention on inner turmoil of Gregor, specifically his problems in professional ambit.			Prototype reader's own worldly struggle to make a living from fiction writing, mirrored in reading on Kafka.
Writer (creative)	'Container' Image schema.	Possible feedback from publisher, critics and readers.	(Kafka 2007: 87): "His numerous legs, pathetically frail by contrast to the rest of him, waved feebly before his eyes."	To centre the reader's attention on the inner struggle facing Gregor Samsa, and thereby showcase his social critique of society in which he lived.	Kafka's own struggle (at wave 1) to make a living for his family, with a job which he detested and which he felt stopped him from his writing vocation.

Thus Gregor comes within reach of a possible escape from the claustrophobic family surroundings which seem to be hindering him from finding a solution to his altered condition (Kafka 2007: 102):

“Gregor dropped with a short cry on to his many little legs. No sooner had this happened, than for the first time that morning he felt a sense of physical well-being; the little legs had solid ground under them; they obeyed perfectly, as he noted to his satisfaction, even seeking to carry him where he wanted to go; and he was on the point of believing a final improvement in his condition was imminent. But at that very moment, while he was still swaying from his initial impetus, not far from his mother and just in front of her on the ground, she, who had seemed so utterly immersed in herself, suddenly leaped into the air, arms wide, fingers spread, and screamed: ‘Help, oh please God, help me!’”

The figure of the mother, to whom Gregor shortly thereafter ‘softly’ looks up, thus hinders the insect from chasing after the chief clerk down the stairs. In receptive terms, the reader finds out that the ‘container’ of the metaphoric insect-body is now working well, and is even giving Gregor a sense of well-being and satisfaction for the first time that morning. The reader thus links a movement towards the outside world with a positive emotion on Gregor’s part. But at this stage the mother stops Gregor’s escape from the container that is the flat. She does this by appealing to Gregor’s emotional bond in the mother-son relationship. It is a mental appeal.

The appeal is directed at the container that is Gregor’s head. Thus we have a prototype reader inundated with limitations within these containers discussed above, creating an accurate reading resonance of the way in which Gregor is trapped within these inter-linking family-professional ambits that stops him from unfolding his full potential and breaking out to face the world on his own terms.

Despite this emotional restriction of Gregor’s freedom of movement and actions by his mother, the prototype reader is again given an inkling of hope that the family will now finally actively attempt to help Gregor. This sense of hope is activated by the reader’s own input of motherly love, and comes just as the mother is shouting for divine help. In that shout, though, also lies the essential negation of this hope. The receptive skepticism sets in the split-second thereafter. How will a mother help her son, when all she is asking for is help for herself? The writer’s word choice is effective here in showcasing the selfishness of the Samsa family, all the more so when the dictatorial father figure who many literary critics have linked to Kafka’s own life takes the chief clerk’s cane and a newspaper (Kafka, 2007: 104) as he “attempted to drive Gregor back into his room.”

The prototype reader registers this negation of Gregor’s drive for freedom all the more acutely because of the aforementioned focus on the container that is the insect body. This means that the reader is also being hassled back into the original, constrictive container with Gregor: the room in which he first woke up as an insect.

Again, moving swiftly from the receptive analysis to that of the production level choices of the writer, we are confronted with the highly symbolic imagery of Gregor’s father utilizing both a newspaper and the chief clerk’s cane to force the unwanted insect-son back into the hidden container of his bedroom. Power in the professional ambit merges here with power in the familiar ambit. This power is concentrated entirely in the repressive father figure, who later also physically attacks insect Gregor with a hurled apple which becomes encrusted in Gregor’s back. For now, though, the reader is made to consider the powerful imagery of concentrated power brought about by Kafka’s simple word choice at the productive level (waves 2 and 3) of his story, which is visualized in Figure 3 below.

Figure 2. Kafka's 'power' imagery concentrated in authoritarian father figure.

Each of these inter-linking spheres of power, all of which are oppressing the man turned insect Gregor, are effectively merged into a single figure of authority by the writer. The linguistic end product (wave 5) thus showcases the writer's cognitive intention: to show the constrictive effects of overlapping pressures in family, professional and societal spheres on an individual, which is influenced (at wave 1) by the writer's own worldly experiences in dealing with a highly patriarchal father figure and parents who, as Beicken highlights in another of Kafka's letters (2007: 57), were always chasing after him: "I always felt (that my parents) were constantly after me..." It is this sense of unhealthy pursuit which is symbolized by Samsa senior's threatening usage of both the newspaper and the cane to force Gregor back into his room. The reader's last escape option from the nightmarish finale that threatens comes then in the form of the sister whom Gregor seems to have such a special relationship to. As shall become evident in the conclusion section of this analysis which here follows, it is a confounded hope.

3.4. Conclusion: Negating the Reader'S Hopes for a Re-Transformation

From progression to conclusion of the main character's beastly dilemma, Kafka maintains the (albeit threadbare) hope in the reader that Gregor Samsa may at some stage return to his normal human status. The re-transformation is the innate desire of a prototype reader who has taken an entirely bodily identification with Gregor through the writer's emphasis on the 'container' image schema. But as the story nears its conclusion, as Gregor begins to neglect the food that is put out for him and feels entirely alone in a domestic and professional world without an ounce of empathy, it seems, the reader begins to wonder something which entirely justifies Kafka's choice of the insect metaphor: will it even be advisable to return to the status of a normal human being in such ghastly, inhumane surroundings?

By virtually placing the reader inside the container of Gregor's hideous insect body, the reader is constantly left to wonder what final bodily improvement might put an end to this story of human (but ironically essentially inhumane) *tristesse*, and Kafka skillfully positions Gregor's sister Grete as the key persona in this regard. Somewhat freed from the repressive financial and professional triangular relationship which binds Gregor to his mother and father, and glossed with the illusions of Gregor's musical hopes for her which are indeed metaphorically representative of Kafka's own writing ambitions, the sister takes on the role of the saviour. She has, indeed, taken charge of supplying Gregor with his food (Kafka, 2007: 108) throughout the progression of the story 'Metamorphosis'. Even if this task has not been completed with much affection, the sister is essentially the person charged with keeping Gregor alive. All the more shocking is the effect on the reader, then, when after her musical performance for the three visiting gentlemen who have become boarders in the flat (Kafka, 2007: 136), Kafka's sister is the family member who first suggests that (Kafka, 2007: 138): "we have to try and get rid of it. We did as much as humanly possible to try and look after it and tolerate it." The triple salvo of the impersonal 'it' usage by Kafka removes Gregor completely from any semblance of humanity, and with it the last lingering reader hopes for a positive finale to Gregor's ordeal. That it is the sister to whom Gregor is so strongly attached, and who has just recited a musical performance on her violin to which he feels so artistically bound, who gives the reader this final certainty is especially shocking. In receptive terms, thus, the ending promises as much cognitive activation through a variation from the standard – by negating the potential reversal of Gregor's situation – as the beginning did by abruptly producing it in the very first sentence. In the aftermath of his sister's damning words, Gregor turns around and returns to his room – the final return to the 'container' which is such a recurring image schema throughout the story.

From being a place of life and a place *to live*, the room now very shortly takes on the form of another container – that of a coffin. Claustrophobic imagery and word choices (wave 2 and 3) on the part of Kafka insinuate that Gregor's death – both as an insect and as a human being, is near (Kafka, 2007: 141): "What now? Wondered Gregor, and looked around in the dark. He soon made the discovery that he could no longer move...He remained in this condition of empty and peaceful reflection until the church clock struck three a.m. The last thing he saw was the sky gradually lightening outside his window."

A number of receptive and productive level linguistic observations are crucial in the description of Gregor's death. Firstly, the funereal word choices imprint on the reader's cognitive impulses the impression that Gregor's death, and by extension the story's conclusion, are near. Secondly, the time of his death is at precisely three a.m, which is coincidentally (or not) also the number of family members who now remain alive. Finally, Kafka shows first signs of a lightening of the sky at the precise moment when Gregor takes in his last sight. It is a final look out of the futile window to the unattainable outside world. The improved weather is also something which will be accentuated by the writer at the very end of the story. At this stage a rather melodramatic, almost self-pitying imagery is chosen here for Gregor's demise, with the insect's death seemingly bringing light and improvement to the three remaining members of the family. But why did Kafka choose to create this receptive impression in the reader at such a decisive stage of the story?

Deducing an answer to this central question employing the 'Wave Method', it is fair to say that Kafka likely chose a production level usage (waves 2 and 3) of all three features discussed above to reinforce the cognitive writer-reader dynamic with the reader at the most

important stage of the entire story – where Gregor's hopes of becoming a human being again are finally and tragically dashed. The word choice bearing over into a funereal atmosphere just ahead of Gregor's final demise is a skilfully utilized linguistic mechanism to build tension, but also to imprint in the reader's mind an absolutely new question as the first one (will Gregor become human again?) is finally erased: that being, why has Gregor never actively fought against his imminent death? By focusing on the dark prelude to the final death, then mentioning the three o'clock death hour, and finally showing a lightening of the sky when Gregor dies, signifying the dawn of a new, likely better, day, Kafka cleverly hits home his cognitive message as if it were a rusty nail into Gregor's (invisible, and yet omnipresent) 'container' coffin. Kafka's linguistic usage (wave 2 and 3) here implies the primary metaphor which derives from shared human experience; that darkness is negative and light is positive. According to Kafka's linguistic choices, the family simply thinks it is better off without the insect Gregor. The cognitive message offered by the writer here is a stark version of reality, indeed. One far removed from any hope of a reversal, however small or subconscious that hope may be, which Kafka has been building up cleverly in the reader. As Beicken (2007: 76) finds: "His (Kafka's) 'Metamorphosis' destroys every fairytale schema of the magical reverse metamorphosis and negates related reader hopes, even if those were only activated subconsciously." Having thus come to the heart of Kafka's cognitive intentions in implementing the linguistic usage indicated above, it is possible in this case to link this intention directly to the writer's (wave 1) worldly input and own family surroundings. Mueller (2009: 58) writes that "Kafka had shortly before (beginning the story), at the start of October, made the experience that his favorite sister Ottla, who normally always took his side against their father, moved to the side of the family." This notion of betrayal by a sister is then clearly reflected in the writer's created reality within the fictional blend of the man turned insect, who is now finally dead.

With Gregor then well and truly deceased, the final receptive question that remains open to the reader is: why has this terribly tragic metamorphosis taken place? Once again the receptive answer is to be found in the linguistic end product (wave 5), as Kafka brings his story to a stingingly critical conclusion with the aforementioned intensification of the implied primary metaphor (dark is negative, light is positive). In this case, when the three (once again the emphasis on this number is almost overwhelming, despite its simplicity) remaining family members leave the flat for their first walk together in months, (Kafka, 2007: 145) "the carriage in which they sat was flooded with warm sunshine." What might be seen as a simple case of pathetic fallacy in conventional literature analysis is in this case an almost blindingly clear spotlight shone by Kafka into the conscience of the family. Having done nothing to help their struggling son and brother Gregor, the family is now pictured (Kafka, 2007: 145) "sitting back comfortably in their seats." The spotlight has become shrill and unbearable for the reader.

The receptive focus on a simple physical, outwardly description is most certainly centered on the hearts (or lack of heart) of each of the remaining three family members; how indeed, can such inhumanity exist within such a seemingly normal family? Kafka thus concertedly employed the linguistic mechanisms at his disposal to create an overall impression within the reader's mind, one which is not at all positively inclined towards the parents and the sister of Gregor. Whilst Gregor's passivity upon becoming an insect may be explained through his lack of means as an insect, as well as his unsupportive family surroundings, no such excuses are allowed by Kafka for the remaining family members. They

have now symbolically also broken out of the confines of the flat-container, but without Gregor in their ranks.

What might be thought of as a terrible relief for the claustrophobia-induced reader becomes a further restriction in that our focus is entirely centered then upon the mind ‘containers’ of the three remaining family members. There the reader looks in search of the essentially un-answerable question: why did none of the three show any humanity in Gregor’s ordeal? From the Gregor-centricity of the entire story ‘*Metamorphosis*’ up to this point, brought about by a concentration on the container that was Gregor’s horribly effective (in cognitive receptive terms) new body, Kafka now necessarily shifts the focus to the remainder of the Samsa family, thereby effectuating his cognitive intentions of showing the self-constricting circles which domestic and professional pressures have drawn around his tragically deceased hero. The productive level choices of the author indicate, quite clearly, that a new, brighter future is now set to begin for the Samsa family.

Thus, Kafka’s choice of a flower metaphor (at waves 2 and 3) for Grete in the finale of the story has a powerful message to convey, namely that a new beginning now seems to be awaiting for the three survivors of the terrible fictional transformation: (Kafka, 2007: 146) “she had bloomed into an attractive and well-built girl.” The flower of spring, the flower of youth, the flower of peace, but also the flower of irony is planted in the reader’s mind by Kafka’s simple cognitive choice of this very basic metaphor, which shows no great variation from the standard (as can be seen in table 6 which follows). But there is no need for complication here. Kafka very simply illustrates with this flowery metaphor, seen indeed through the eyes of the parents, how positive the family future has supposedly become after Kafka’s death. The transformation from the beginning of the story, when the entire family was dependant on Gregor’s income to survive could not be more marked.

Gregor’s sister then undergoes a parallel, if slightly less visual transformation in the eyes of the Samsa parents. From being frequently annoyed with her for being “a somewhat useless girl” (Kafka, 2007: 117) to becoming the new hope of the family at the end of the story (Kafka, 2007: 146):

“Falling silent and communicating almost unconsciously through glances, they thought it was about time to find a suitable husband for her. And it felt like a confirmation of their new dreams and their fond intentions when, as they reached their destination, their daughter was the first to get up, and stretched her nubile young body.”

What is described in an entirely neutral resonance – the ‘new dreams’ and ‘fond intentions’ of the parents for the ‘blooming’ daughter, is receptively taken up by the prototype reader as a sinister, self-interested plot to marry their daughter off to receive financial benefits of their own. Indeed, the development of the story up to then has virtually confirmed that these are almost surely the intentions of the parents. The reader’s cognitive apparatus thus subconsciously merges the experience of the recently deceased Gregor and his treatment at the hands of his parents with the second case of their daughter. Kafka’s description of Grete’s ‘nubile’, flower-like body at the very end of the story contrasts wonderfully with the hideous monster, no more, which awoke at the beginning to our shocked disgust. Receptively, the prototype reader is at once relieved and appalled; the latter by the parent’s terribly egoistic attitude in now placing their focus on Grete as the source of family income, the former by the outwardly appearance of beauty and serenity which Gregor’s sister transmits.

Table 5. Use and effect of ‘flower’ metaphor in conclusion of Kafka’s ‘Metamorphosis’

Actor	Linguistic device	Receptive effect	Productive choice	Cognitive intention	Worldly input
Reader (receptive)	‘Flower’ metaphor.	Flower activation produces receptive contrast with ugly insect at start of story.			Own experiences of the beauty of flowers blooming.
Writer (creative)	‘Flower’ metaphor.	Possible feedback from publisher, critics and readers.	(Kafka, 2007: 146) “she had bloomed into an attractive and well-built girl.”	To provide contrast at end of story; beauty of flower metaphor against the hideous insect metaphor chosen at the start of the story.	Kafka’s own experience shortly before writing of story in which his sister sided with parents rather than him.

Kafka, in bringing the story to an entirely fitting ending with the last word ‘body’, again concentrating on the ‘container’ image schema which has had such a central linguistic focus throughout, has created a story in which one family member is effortlessly exchanged for another when he ceases to be useful. This reverts back to Kafka’s worldly input and cognitive intentions of criticizing a society based on superficiality and outer looks, and one not overtly concerned with inner love and familiar caring. As Schwarz succinctly writes in his afterword to Kafka’s magnificent story (Kafka, 2009: 78): “Above all the story showcases the tyranny of an economic system, which is based on the slavery of the soul, and which only recognizes one law, the law of profit.” A story then, which is as relevant today as it ever was in Kafka’s lifetime, and which unfolds an almost magical writer-reader dynamic with the long deceased author from Prague.

A final consideration must then go to the unresolved question which Kafka purposefully left open to the reader’s imagination: why transform a man into an insect? Why indeed did this transformation take place? The reader is given no explicit hints, but must use their own cognitive ability and deduce the answer from the implicit meaning of a story that has become part of literary world heritage for its creative usage of an extended metaphor; that of the man turned finally and fatally insect. This piecing together of meaning both feeds from a long literary tradition of transformations, and also shows the necessary creative variation that captures the reader’s cognitive attention with its failure to bring about the final reversal of the hero’s metamorphosis. When Hogan (2003: 80) finds that: “the two transforming conditions that differentiate childhood art from adult art: technical mastery and audience awareness”, we can after this writer-reader dynamic analysis safely suggest that Kafka performed both with exquisite skill and created in his relationship with the reader a final, fitting burst of understanding: Gregor was transformed because his professional and domestic worlds transformed him, and then never gave him the chance to return to humanity. As Fechter (1952: 488) explains: “*Die Verwandlung* ist das erste Beispiel des deutschen Surrealismus, Abloesung des Stofflichen von den Bindungen der sogenannten realen Welt, Verneinung alles

positivistischen Glaubens an eine alles verpflichtende rationale Ordnung der Natur...’’⁸ The reader’s cognitive link to the real world mentioned by Fechter is thus severed ostensibly by Kafka at the very start, but it is never essentially broken. Gregor Samsa’s metamorphosis is essentially a worldly one, and Kafka, the writer struggling to find enough time to write his magical stories in between professional commitments, could not have been better placed to write it.

CONCLUSION

Having thus examined one of the essential 20th Century literary works, the current section aims to draw together key findings of this study. But before moving on to these most significant findings derived from the ‘Wave Method’, it is opportune to consider the words of Mario Vargas Llosa when he said that:

“When writers are alone, to interrogate themselves, they know that as much effort as they put into it, and as far as they got, the work still remains below the ideal of absolute perfection and absolute beauty which a writer, and any artist, always want to achieve. But the marvelous thing about literature is that it is the magic which we find in order to live these worlds of absolute perfection, absolute coherence and absolute beauty which we can never live in the reality. When we read ‘Don Quijote’, or ‘War and Peace’, or Joyce or Faulkner, one of the great works of literature, we don’t only read but we effectively live this reality through a character, a reality where everything is beautiful, even the most ugly, cruel things. During the time of reading we are able to abandon the world and enter these perfect worlds, I think that is one of the marvellous things of literature.”⁹

Not only does this show the restlessness and discipline which drives a great writer like Vargas Llosa¹⁰, but it also displays the extent to which a reader is transformed into a state of bodily identification with the main character in successful works of fiction.

From the very outset of the Results the ‘Wave Method’ analysis of ‘Metamorphosis’ has shown Kafka’s reliance on the transformed body of Gregor Samsa in making a heightened impact upon the reader’s receptive system. This choice of the ‘container’ image schema brings about the effect of ‘embodiment’. Indeed, the fictional blend which is created by the author is of a counterfactual nature, but works with a real sense of authenticity due to the writer’s choice of resonance in the writer-reader dynamic. Thus, the prototype reader knows

⁸ “The ‘Metamorphosis’ is the first example of German surrealism; removal of the material world from the connections of the so-called real world; negation of all positive belief in an all encompassing rational order of nature.”

⁹ Translated from the Mario Vargas Llosa speech at ‘Conversacion en la Universidad’, event during the ‘I Semana Complutense de las letras’ in Madrid on May 4th 2011.

¹⁰ A notion discussed in my article published on May 7th 2011 in El Pais English: <http://blogs.elpais.com/transiberian/2011/05/mario-or-the-great-writers-wrestlessness.html> Extract from article: “And the master did not disappoint. He talked of the writer’s omnipresent insecurity. He joined together beautiful sentences, as if indeed writing in the air. And he complained that the Nobel Prize has taken away his time for writing, and at times even his energy to do so. And therein lay the essence of Mario’s restlessness on this balmy Madrid spring evening. No writer, he said then, could ever be completely satisfied; with their work, with the time they’ve invested, with the effort they’ve made.”

that this is physically impossible, but wants to believe in the blend because of the harsh reality which has befallen the main character in Kafka's 'Metamorphosis'.

This linguistic mechanism chosen by the author therefore effectively places the prototype reader into Gregor's body to bring about the receptive effect which Vargas Llosa was referring to in his above mentioned talk in Madrid. As Hogan (2003: 73) found: "These standard cases (thus prototypes) are often altered in one or another particular way in the works that are considered lasting...". Hence Kafka's focus on the body of an insect very much serves to create disgust and repulsion in the receptive equation of the writer-reader dynamic. When Oatley (1992: 107-8) wrote that "people can mentally simulate the plans of others and understand their emotions, just as they can run simulations of their own plans...", he also added to this the following specifying sentence that: "we need to postulate that a person can identify with a protagonist taking on goals and plans as if they were his or her own as a narrative unfolds." On the other hand, Tan (1996: 98) concluded that an interest in narrative only exists if the receptive party is able to envision a number of possible outcomes as a result of the narrative, and also if it is continually possible to test these outcomes in terms of probability. Finally, Tan thought it necessary for a sense of progress to be made towards a closure, or what he referred to as the preferred final outcome. It is noteworthy also in this regard to consider that Hogan (2003: 166) identifies two major features which engage readers in the narrative: "The first is the ongoing appraisal of changing conditions relative to goals. The second is the activation of episodic memories." The question which developed as the current study progressed, thereby showing that outcomes were not being predicted but rather ascertained, was the following: does a reader subconsciously create cognitive questions with regards to the outcome of the novel during the reading process? The response in the case of the prototype reader was that this was indeed the case, and that these questions were then actively resolved in the reading process; from title, to beginning, progression and conclusion of a work of fiction. These cognitive questions, developed subconsciously in the reading process and discussed in detail in the Results, are thought by this study to be of central importance in what Hogan (2003: 173) refers to as the 'orientation threshold': "Passing beyond the orientation threshold is literally what keeps our attention. Without that we drift away, lose interest, and stop reading."

It was mentioned in the analysis that the English translation of Kafka's originally German language 'Metamorphosis' employed a translation of 'monstrous cockroach' for the German '*ungeheures Ungeziefer*'. The translator and linguist interviewed for this study, Enrique Bernárdez (2008), found in this regard that:

"I think in that case, the translator has done too much, because Kafka never wanted any particular animal to be identified. So if the translator writes cockroach, then the interpretation of the whole story is being led in a certain direction, so that you identify the animal already at the beginning. That is wrong; I think 'bug' or something would have been a better translation. I don't know how it is in the Spanish translation, but I think they use a word like 'insecto monstruoso' or something like that. This is much better. Otherwise the translator is guiding you too much in a certain direction."

What emerges from this example, which is found in this study to be of central cognitive importance in a receptive regard due to the central nature of the insect in this story, is that the translator (wave 4) and by extension publisher can have an equally important input in the

writer-reader dynamic. Thus for example the German language reader of this story would have one particular set of cognitive activations and associations, depending also upon their worldly experiences, whilst the English language reader will necessarily have another, in this case more specific, activation. In bringing a piece of fiction to a far broader audience, the work of the translator is indeed of much importance in the entire creative writing equation, but it may also bring about a different cognitive reading experience in different languages, and by extension different cultures.

Thus it has here been seen that the ‘Wave Method’ presented has not only a firm grounding in existing linguistic theories, but can also provide a valuable form of coming to what seems to be an accurate interpretation of the writer’s cognitive intentions in penning a particular work of fiction.

Chapter 84

APPROXIMATIVE SPACES AND THE TOLERANCE THRESHOLD IN COMMUNICATION

Barbara Lewandowska-Tomaszczyk

University of Lodz, Lodz, Poland

ABSTRACT

The paper substantiates the concepts of meaning re-conceptualization and approximation in communication as put forward in Lewandowska-Tomaszczyk (2010, 2012 in press). The present discussion locates the phenomenon of approximation in cognitive domains and shows the contents of approximative spaces, allowable substitutions in the domains as well as their tolerance threshold, and discusses the circumstances in which this process is evidenced in communication.

Keywords: approximative spaces, communication, polysemy, reconceptualization, similarity (resemblance), synonymy, tolerance threshold

1. INTRODUCTION

The concepts people use in communication exchanges are more often than not only partially overlapping. There are a number of reasons for such a state of affairs (section 3.1.). The paper takes up and extends the notions of *cognitive domains* and *mental spaces*, first proposed and elaborated on in Cognitive Linguistics by Gilles Fauconnier (1985). Its focus is on presentating the relationship between the content of a prototypical (default) cognitive domain on the one hand and its on-line dynamicity in ongoing interaction on the other. The primary role in this process is attributed to the nature of meanings, used and exchanged by the Speaker and Addressee. The crucial concepts in the exchange are the semantic relations of *identity*, *similarity (resemblance)* or *equivalence* between forms which are considered identical or comparable by the interactants. The concept of similarity, which is the basis of all categorisation processes, forms a multi-peaked radial category space with a number of *tertia*

comparationis, or points of reference, which serve as conditioning parameters in interaction (see *Common Communicative Platform* section 5 and the *threshold properties* in 6). It is argued (similarly to Shepard 1987 and Gardenförs 2000) that, conceptually, similarity is a mapping of physical distance on a cline between the Speaker's and Addressee's conceptual spaces, containing objects, relations and events. Discourse participants manipulate the distance – either by shortening or by lengthening it, although the prototypical intention of the interactants is to reduce the distance between meanings (Grice's 1975 *Conversational Maxims*). They use numerous strategies (synonymy, paraphrase, polysemy, super-/sub-ordinate category members, etc.) to achieve this communicative goal. Some approximating strategies can appear to be, intentionally or not, a failure when they cross over a conceptual-discourse tolerance threshold (sections 6 and 7), which makes successful communication difficult or impossible.

2. TYPES OF COMMUNICATIVE CORRESPONDENCES

Communication can be either *symmetric* or *asymmetric* (Lewandowska-Tomaszczyk 2012a). Symmetric communication involves using identical (similar) meanings by discourse participants, while asymmetric correspondence assumes smaller or bigger divergence in meanings conveyed by the same form. Fully symmetric, i.e., *closely aligned*, or *parallel*, communication between interactional partners is not frequent. Much more frequent are *asymmetric types* of interaction with two opposing poles, one - more schematic, *coarse-grained approximative correspondence of generalized alignment* on the one hand and an asymmetric *particularization relation*, i.e., *fine-grained alignment* on the other. They form larger bulks of authentic discourses.

There are a number of reasons for such a state of affairs. One of them is the fact that some of our thinking tends to be more *effable*, i.e., possible to express in a language, while a large part of it such as some image-verbal thoughts, visions, emotions or dreams remain more felt than expressed, more imagined than put in words. Katz's Principle of Effability (1978), proposing that every thinkable thought in natural language can be encoded and expressed by a sense of some sentence in language, does not stand up to criticism pronounced by semioticians, philosophers and linguists of different denominations (e.g., Sperber and Wilson 1995). Thus, what is communicated verbally to the addressees is not in one-to-one correspondence with our thinking and intentions. Another crucial parameter of approximation is connected with the language typological parameter – a linguistic type a given system represents, in which some ontological categories are verbally marked and can be expressed, while some others are absent or left non-verbalized in the system. Connected with this is the type of a linguistic construction in which the speaker can (considering the typological differences) choose to convey a message. The construction too symbolizes a particular semantic perspective conveyed by these forms via different *profiling* and cognitive *construal* of a given scene or event (Langacker 1987, 1991).

A stable characteristic observed in interaction is the lack of an invariable symmetry in the scope and range of conceptual-semantic spaces across discourse participants. This condition rests within the sphere of the speakers' *knowledge of the world* and the breadth of their respective concepts. *Speaker's intentions* too are relevant here as the degrees of expression of

thought are also a matter of individual intention. The speaker may not wish to share all thoughts, feelings, etc. linguistically (or otherwise) with the interlocutor. Last but not least, the phenomenon of approximation is related to the speaker's *linguistic repertoire*. First of all, speakers have as a rule varying language repertoires which overlap to different degrees and some may be more and some others – less, faithful portrayals of the speakers' thoughts which they are prepared to share with others.

Apart from this basic conditioning of communicative approximation, there are also other, psychological and psycholinguistic factors, like memory lapses, interruptions, and the like, which are partly responsible for the processes of approximation and re-conceptualization.

3. IDENTITY, SIMILARITY, EQUIVALENCE?

Even when expressed in the same linguistic form, meanings different discourse participants use in a communicative act are most frequently not identical. The first approximation phase runs between a stimulus and its mental representation. Speakers then observe and actively produce conventional forms divergent from their original thoughts (e.g., in politeness strategies, due to poor linguistic repertoire, in consideration of face work and the like). In such cases, they tend to resort not to what they would consider the first and most adequate expression of their thoughts (which would not always be possible as pointed out above also for language-specific reasons) but they use a linguistic form, which approximates rather than fully reflects their communicative objective. In other words, the speakers choose, volitionally or automatically, a second, third, or n-th best of what they wanted to convey.

3.1. Liberty at a Linguistic Sign Interpretation

The semantic scope of an individual interactant's meanings leaves an uncovered space in the interpretation of a message (a sign), as a part of a respective organization of mental structures. Its exponent is a system (language, visual system), which is complemented by *inferential structures* – an ability to complement a message with further (unexpressed) thought(s) or image(s). A sign then is by its very nature *metonymic* (only part of the message is explicitly expressed) and frequently *cubist* (message organisation is not necessarily iconic). It can either represent the whole by focusing on its part or it can represent the whole from a number of perspectives and diverse points of reference simultaneously.

There is some evidence of the presence of such originally partly verbalized mental processes with language users. In her experimental findings, Seana Coulson (2000: 12 with reference to Anderson and Ortony 1975) identifies more detailed information in subjects' recall of a message than given in the message itself. Even though they heard the first of the two sentences (1), they particularize it in the task of retelling the same story (2):

- (1) A fish attacked a swimmer
- (2) A shark attacked a swimmer

Another finding (examples 3 – 5, Coulson 2000: 11) refers to the subjects' activation of an object image, in this case, a ball, known to be of a different size and shape in each of the cases, contextualizing it from their knowledge of the world and experience to the basketball, football, and baseball frames respectively, notwithstanding the fact that the form used, as well as its possible core meaning, is invariably a spherical object using in playing games, i.e., *ball*.

- (3) Shah dribbled past his defender and dunked the ball easily
- (4) Joe kicked the ball and smiled as it sailed through the uprights
- (5) Sammy hit the ball right out the park

Such particularizing knowledge frames as the ones above - in this case an activation of an Idealized Cognitive Model (cf. Lakoff 1987) of a respective game – fill in details of the originally uninhabited parts of particular mental spaces.

Some other cases involve symbolic structural and constructional properties in language. Examples include the asymmetric relations between words and their definitions, structural and lexical ambiguities such as in *He could do it* (with the ambiguous *could*), or *Picasso lives here* [non-/metaphoric *lives*] or subtle differences between infinitival and gerundive constructions in English (*Alice started to move/moving her leg*) as well as construal differences forwarded by word order, structural and categorial grammatical difference (*John washed the dishes/ The dishes were washed by John – The dishes wash well*).

Parallel alignment or, in other words, *schematic structure-preserving* representations are primarily present in visual, three-dimensional models of objects, maps, diagrams or tables and express a *resemblance* of different types, although not identity, between a model and a thing modelled. In linguistic exchanges they are used in interactional exchanges between closely cooperating specialists, family members, etc.

Particularisation, i.e., making meanings more precise, involves both conceptual *depth particularization* when the speaker reflects on the meaning and goes deeper into the original context as well as *width particularization* when the meaning is extended to create *new* conceptual links. Frequent examples are scientific and technical definitions, even though the definitional equivalence between the entity named and its definition cannot be considered semantic *sameness*, as for instance in the explanation concerning Einstein's (1905) $E = mc^2$ formula (6).

- (6) In physics, **mass–energy equivalence** is the concept that the mass of a body is a measure of its energy content. In this concept the total internal energy E of a body at rest is equal to the product of its rest mass m and a suitable conversion factor to transform from units of mass to unit of energy. If the body is not stationary relative to the observer then account must be made for relativistic effects where m is given by the relativistic mass and E the relativistic energy of the body.

In such cases as above the definition lacks a relative discreteness of the lexicalised (defined) form, while its wording contains an additive semantic surplus, due to the inferences on individual lexical units used in it and not present in a corresponding single form.

3.2. *Almost and More-or-Less Categories*

I distinguish between two types of structures in discourse: *almost* structures and *more-or-less* structures. This distinction is inspired by an original differentiation presented for two types of mathematical solutions, proposed by Sossinsky (1986), paralleled, as I see it, by the natural language categorization processes.

The *more-or-less* cases in linguistics (sometimes called *approximative solutions* in mathematics) can be defined as ‘an approximation of an exact solution’, in the cases when full meanings are *accessible*. They are approximative by speakers’ intentional choices, by their restricted language code, etc. The *almost* solution in mathematics on the other hand is used in such cases when *no exact solution* exists for a given equation (Sossinsky 1986). Transferring this to language, we would say that in the latter case full meanings remain simply *undetermined* or *vague*.

In language then some meanings are of a more-or-less approximative type when contrasted with their fully accessible sets of properties as in the case of the word *boys* in *Boys like to fight*. Some other linguistic meanings will be of the *almost* type, in which accessible criteria are *either* necessary or sufficient; essential, typical, or else culture-specific or idiosyncratic as in the well-known instance of *game*:

(7) Games are activities which provide entertainment and amusement.

4. SEMANTIC SIMILARITY AS A FUNCTION OF DISTANCE

The concept to be discussed is that of *similarity* (also called *resemblance*). It is used in two contexts. Firstly, in the context of monolingual exchanges, when interactants use the same forms while the meanings they use do not always need to be identical (user-specific polysemies) or in their use of various synonymic forms on the lexical, sentential or paragraph levels. Secondly, in bi- or multilingual contexts, such as inter-cultural encounters or translation, when the interactants or translators employ what they consider translational equivalents on various language levels. Even though the two contexts are most frequently discussed disjointly in linguistic literature, the phenomenon (similarity – equivalence) should rather be perceived in terms of quantitative rather than solely qualitative differences. In the present paper the focus is on the former, while the translational context was discussed in another work (Lewandowska-Tomaszczyk 2010).

I want to propose, after Shepard (1987), that *similarity is a function of conceptual distance*,¹ either within one conceptual space, or across different spaces, where by *conceptual space* I mean, similarly to Peter Gardenförs (2000), *a set of quality dimensions*, either separable (like shape) or integrated with other dimensions (like colour and shape together). Similarly, conceptual spaces are described in terms of *topological geometric objects*. Geometrically, identity, resemblance and difference are captured by the basic notions of

¹ More precisely, Shepard (1987) claims that “there is a robust psychological law that relates the distance between a pair of items in psychological space and the probability that they will be perceived as similar. Specifically, this probability is a negative exponential function of the distance between the pair of items”. (formulated by Chater and Vitányi 2003: 347).

betweenness and *equidistance* (Gardenförs 2000). In logic, these notions are captured by the *near set theory*, whose applications to Content-Based Image Retrieval (CBIR) can be consulted in Henry and Peters (2007). In cognitive and conceptual models the concept of resemblance with the properties common between object and those that differentiate them can be accounted for in terms of varying *construal* and *perspectives* and as different *levels of concept granularity*. Conceptual similarities and differences can also be represented in terms of quantitative (corpus) data, interpreted by means of multifactorial analyses (see Lewandowska-Tomaszczyk and Wilson 2010 for cross-linguistic comparison of emotion concepts). Visualisation of similarity-based conceptual distances can be achieved by different tools (e.g., Lewandowska-Tomaszczyk and Tomaszczyk 2012, and later in the present section, see (9)).

In modeling conceptual spaces we take, after Gardenförs, individuals - people or objects - together with sets of the attributes and properties on individuals to be the primary concepts. Each of the attributes is associated with a particular value set and each value has a certain admissible tolerance region (space), with context-bound upper and lower thresholds. Meanings are thus considered here to be networks with a certain *tolerance space*.

In communication, tolerance spaces are dynamically construed from the level of a conventional prototype up to a (context-specific) tolerance threshold, beyond which a miscommunication or a communicative boycott occurs. The simple concept of say a *tall man* (8) will thus occupy a space of a culturally determined prototype of *tall*, between the spaces *short* and, say, *gigantic* as lower and upper bounds on an *acceptable tolerance region*.

(8)

tall man

GIGANTIC

GIGANTIC [c2]

 tall + 2
 tall + 1
TALL [prototype in context 1]
 tall - 1
TALL [prototype in context 2]
 tall - 2

SHORT

SHORT [c2]

In the structures representing objects and relations described above, some objects which fall *within* a given structure, represent *allowable substitutions*. They have to be *sufficiently similar* for a given activity/discourse objective to allow a substitution. The similarity is perceived and conceived by language users taking various criteria into consideration (Lewandowska-Tomaszczyk 2010). Similarity (resemblance) is perceived in terms of perceptual, functional, axiological, ideological, inferential (logical), etc. criteria. Inferentially,

speakers can refer to metonymic (partonymic), metaphorical, etc. properties and, provided they are shared by the interactants, the properties will be considered allowable substitutions.

Following this line of reasoning we could propose that some concepts tend to go together in utterances, in that they are treated as *substitutable* in some contexts, and form *conceptual clusters*, which show strong similarity links both within the same concept and across different concepts within the cluster. Below in (9), a *clustering network* is presented in an exemplary instance of the multiple polysemous lexical form *train*, as generated from the BNC data. The graph is generated by the tool *Infomap* demo version, developed by Stanford University team and representing *corpus-based vector space models* – *Latent Semantic Analysis*, which employs word co-occurrence matrices.

What can thus be observed is that the concepts such as *train* will be a part of a whole cluster of senses, with a strong position of the notion of *station*, on the one hand but also *subway*, and *bus*, with the foregrounded concept of *rail*, on the other. *Train* is also polysemously linked to *education* and *drill* (training), the latter, again polysemously, associated both with *practice* as well as *oil* (see Lewandowska-Tomaszczyk 2007 for a typology of polysemy). These polysemies are present in English but not necessarily in other languages. For such radial structures what can be identified are the *closest members* (<http://www-csli.stanford.edu/semlab-hold/infomap.html> Latent Semantic Analysis), in which degrees of semantic similarity can be calculated and defined with numerical values.

(9) Infomap *train* cluster

Relevance of such similarity clusters for communication is observed when language users replace one unit for another, which display a closer or more distant semantic similarity as e.g., in *The teacher **practices** spelling with the learners* – *The teacher **drills** the learners in spelling*. It has to be emphasized that such forms (*practice* for *drill* or, in *job* for *business*, *labor* or *service*) are not synonyms *sensu stricto*, but they can function as practical approximations in authentic language contexts, i.e., as synonyms *sensu lato* (see also Tomaszczyk 2012).

4.1. Reducing the Distance: Meaning Precisation

In communicative contexts interactants prototypically make an attempt, with different degrees of success, to reduce the semantic distance to achieve full(er) understanding (examples from Quirk and Svartvik 1980):

(10)

S.2.9

P. 604

a 626 general science, eh, general medicine now I thought was the non-elitist –

A oh NO, it's very ELITIST

a I thought it was the specialists who are elitists

A but general medicine is a SPECIALITY... I mean. m ...general MEDICINE.

Eh people don't . it's very INTERESTING, everybody KNOWS what a general SURGEON is – I mean everybody knows what em – a paediatrician is or a GYNAECOLOGIST..but it's very INTERESTING people don't REALLY know what a general . PHYSICIAN is . it's a PHYSICIAN – it's dealing with TREATING people . who's got DISEASE who don't need SURGERY – and that includes –

B it's quite different from a general PRACTITIONER

A oh YEAH . m . a general PRACTITIONER will refer patients to – ehm a general PHYSICIAN – a general physician well – uses DRUGS . I mean that's his main . you know he doesn't CUT . he uses DRUGS. And he'll treat – he'll treat DISEASES – such as – INITIALLY a duodenal ULCER . 656 ehm – cardiac FAILURE

A following set of properties, typical of a general medicine specialist as opposed to general practitioner, can be extracted from the above exchange:

(11)

Properties of a General Medicine specialist:

elitist

specialist

treats people who have a disease and don't need surgery

uses drugs to treat

The exchange is not exhaustive and leaves the interlocutor with an approximative picture of the differences between the two medical specialities. The questions unanswered refer to the status and position of GP in medicine (*Is s/he a non-specialist? Doesn't s/he use drugs to treat? Does s/he simply refer patients to other medical doctors?...*).

Other examples fall within the realm of definitional approximations. The example below presents an implicational meaning of the phrase *short sighted* (Quirk and Svartvik 1980), with the repeated attempts to decrease the semantic distance between the interactants (12).

(12)

SHORT SIGHTED

S.2.5. p. 311

A do you [d] do you DRIVE

C NO I'm too SHORT_SIGHTED to drive – NO

A what with GLASSES you can wear GLASSES

C OH YES I WEAR them but I'm EVER so short-sighted even with GLASSES
on

B INSURANCE - - - yes I don't really UNDERSTAND that Jacqueline actually
I thought glasses could normalize almost ANYBODY's vision

C well they CAN'T ACTUALLY

B OH

a why not

C well because I'm just too – haven't got the CAPACITY to

B obviously they can't if you're BLIND there must be SOME limit

C (laughs) WELL I suppose I'm semi DEMI SEMI-PURBLIND then

B SAND blind a nice word we had last WEEK

a [m]

C YES cos AFTER all I can – YOU know I can READ - - - I can't judge
DISTANCE at ALL

B THAT'S interesting does that mean that one of your eyes is different from the
OTHER one cos that's all done by SCHOOLS

C well YES but I think you KNOW I didn't have GLASSES till I was ten I
never really developed stereoscopic VISION – I was one of those CHILDREN
who are always falling DOWN

The analysis uncovers the following network, in which the relevant concepts adopt the dynamic values:

(13)

FULLY SIGHTED

Vision perfect (Agent can drive with no correction)

SHORT-SIGHTED

Vision imperfect

Vision can be repaired with glasses (Agent can drive with correction)

'SAND' BLIND [DEMI SEMI-PURBLIND]

Vision imperfect

Distances misevaluated

The crucial definitional part of the latter condition turns out to be the particularization of the default from:

Vision can be corrected with glasses

into:

Part of vision - crucial to driving - cannot be corrected (Agent cannot drive)

This property opens up a similarity space between *sand blind* and (*genuinely*) *blind*:

BLIND

Absence of vision

Vision cannot be repaired with glasses (Agent cannot drive)

What has to be emphasized is the fact that interactants use approximative, underdetermined senses in their exchanges and yet these meanings are often considered *sufficient for the context in which they are used*. Discourse participants can thus be satisfied with the fairly coarse-grained level of semantic specificity in their exchanges. Linguistic markers of approximateness are numerous and are often used by language speakers to signal the divergence from the level of symmetric (parallel) alignment. The markers include conditional clauses, phrases such as *so-called*, *you know*, *I don't need/want to mention the fact that*. The intentional use of vagueness, ambiguity, or implicit reference to background knowledge are also common discourse strategies in such cases.

Language users make an attempt to reduce the distance between the scope and range of the speaker's and addressee's meanings by making them more precise when needed, i.e., when they are able to, they see a reason to do so or when they consider it relevant to the interlocutor as in self-corrected utterances *He came in or rather slipped*. Nevertheless, this does not always take place and as a consequence, not always would full comprehension be achieved.

The conditioning for *semantic approximation* is exemplified in authentic language data and analysed in the following section.

5. COMMON COMMUNICATIVE PLATFORM

5.1. Parameters in Approximative Communication

From the above discussion we can conclude that approximative communication, Gestalt in nature, aims either at best approximation possible under given conditions or at more-or-less communication.

In the Polish example '*planujemy potężne burze i możliwe podtopienia jutro*' Eng. 'we plan (for) huge storms and possible flooding tomorrow', the Speaker chooses the form implying a conscious planning on his part, from the semantic field of futurity, even though his agentive role in such a scenario is naturally questionable.

The Speaker can also choose an approximative form for rhetorical and emotive purposes, to impress the audience, surprise them, etc., or for connative reasons, to persuade the audience or impose an ideology. This frequently takes place in the trading scenario in the case of advertisements.

The common technique is understatement and the use of information selectively (*We sell the best beer*). In some other contexts language is produced automatically in chunks, predominantly in spoken discourse, with weaker control by the Speaker, so the outcomes are certain conventional routines (e.g., *I'm sorry*), not necessarily in one-to-one correspondence with the nuances of relevant intentions.

In the examples to follow (ex. 14-16), extracted from the spoken subcorpus of the National Corpus of Polish, the discourse markers of approximateness used are in the form of distancing markers (*tak zwane* 'so-called'), making resort to a common pool of knowledge (*no wiesz* 'you know') (14), introducing negation for rhetorical reasons (*już nie wspominam* 'I don't even mention') (15), or imposing a hypothetical or even possibly counterfactual but probabilistic scenarios (inviting invalid presuppositions) as in (16), or in numerous other cases, using vague, ambiguous or not fully determinate expressions as in (17) in the section to follow.

(14)

A: to jest coś takiego że u nich jest już to wykształcenie wyższe u nas dopiero jest po magistracie..

B: nie u nas też jest wyższe po licencji. normalnie tak? no to jest **tak zwane** wyższe tylko **no wiesz** takie no. zawodowe no..

A: 'with them it [BA diploma] counts as tertiary education, while with us – you are a graduate after you have your MA'...

B: 'No, we also have tertiary BA education diploma after we graduate from a licenciate (i.e., BA) programme. It is also **so-called** higher education but **you know**, rather vocational'

(15)

już nie wspominam o wyposażeniu tam ale chodzi wiesz o takie [...] zawieszenie
'I don't even mention the interior design but the thing is alignment'

(16)

bronimy krzyża

'we defend the holy cross' [*defend* implies a real or imagined enemy]

6. CONSTRAINTS ON SENSE DIVERGENCE: THE TOLERANCE THRESHOLD

Linguistic modification phrases can have a fairly wide scope of reference, e.g., the nominal phrase *red pencil* can refer to the pencil surface, pencil graphite part or both (see Langacker's 1993 for *active zones* or *reference points*).

The phrase is underdetermined outside the context even though it refers to a fairly steady element in our surrounding. Other lexical combinations are subject to even more varied possible interpretations, which is one of the sources of semantic approximation. The example

below contains one such example referring to the content of the forms *bicycle* and *peasant's bicycle*:

(17)

I have finally learned what upset Jiang and Miss Li so much about my choice in bikes. I thought my bike looked very standard, exactly like 95 per cent of all the other bikes in Chengdu-black, 28 inches, a man's, no gears of course, the caliper lock on the back wheel. I chose it over a dinky 24-inch woman's model like Miss Li's because it reminded me of my own Raleigh (on which, I hear, Chinese bikes are modelled). But this week, as I was getting on my bike outside the Foreign Language building, a student in the department came up and started chatting. His eyes kept straying to my bicycle. Finally he touched it and said, "*Why did you buy a peasant's bicycle?*" "*A peasant's bicycle?*" I asked. "*What do you mean?*" He showed me the two extra steel rods that run between the hub of the front wheel and the centre of the handlebars. Of course I had noticed them, but I didn't know what they were for. "*These are to make the bike stronger, for carrying heavy loads,*" he explained [italics added]. I realized then, something Jiang and Miss Li would never have told me: I was essentially choosing a bike much *below my status*. Not just a woman, not just an intellectual, but a foreigner-riding a peasant's bicycle. Slowly, slowly, I am beginning to be able to discern the Jaguars from the Honda Civics.

(17a)

peasant's bicycles

(Sources: <http://strebeigh.com/BikesChina.aspx>,
See also: <http://www.youtube.com/user/tofugalaxy>)

The prototypical meaning of *bicycle* evokes a mental image of a vehicle having a frame mounted on two wire-spoked wheels, handlebars for steering, brakes, and two pedals, even if the prototypical details will be culturally modified. The Genitive Plural of the English Noun (*peasant's* here) is notoriously ambiguous among the possessive, agentive, and attributive

senses and the Speaker in (16) acknowledges this multiple ambiguity (approximateness). The socio-cultural knowledge frames concerning the (Chinese) context, characteristic of his interlocutor, impose precision on the conceptual (default) prototype to evoke a more fine-grained image of a vehicle with an extra steel rod attached between the handlebars and the front wheel. As can be identified in large internet visual resources exemplified in (17a) above, there is more than one technical instantiation for the ‘peasant’s bicycle’ possible to construct but the interlocutor chooses to constrain them to one such type. On top of that, a social (pejorative in this case) meaning evolves as an integral part of the more precise meaning.

It can be inferred from the narrative in (17) that the divergence in the interlocutors’ meanings cannot be infinite. The phrase *peasant’s bicycle* can be meant literally or metaphorically with reference to objects, but would be less conventional (thus less frequent), even though naturally not impossible, to be used with reference to abstract concepts. The divergencies are limited by the *degree of resemblance* of particular linguistic signs used in the communication act. Resemblances are culture-, context- and, eventually, speaker-specific. They are both qualitative and quantitative and the variables are not fully, but only by default, predictable outside of context. The original linguistic sign is thus, to a large extent, a determinant of the size of *the possible tolerance spaces with respect to particular attribute values*.

Passing over a *default tolerance threshold* can cause a communication breakdown. Alternatively, the interactants may negotiate the threshold in some contexts and cross the default boundaries (see (18) and (20)). The threshold can either be lowered or heightened (i.e., approximative areas will be narrowed down or widened respectively), depending on the contextual (including attitudinal) factors of the interaction participants. One of the interesting linguistic tests for some of the threshold values can be metalinguistic negation such as in *Tom is not tall, he is very tall*, or *Tom is not very tall, he is tall*. Metalinguistic negation in such cases functions as a threshold determinant for the conceptual boundaries characteristic of individual speakers.

6.1. Inventory of Threshold Properties

The threshold properties are divided into qualitative and quantitative properties. The meanings used cannot diverge beyond them even though the divergence point is not easy and sometimes impossible to determine precisely. The features cover the following criteria or attributes:

- Qualitative features - shape, topology, function, value
- Quantitative features [near sets] – numbers and frequencies of feature values

The objects within the threshold determine resemblance models between the objects compared in monolingual communication or between SL and TL. The resemblance models contain structures representing objects and relations. Some objects considered *sufficiently similar* for a given activity/discourse within particular structures represent *allowable substitutions*. A typology of allowable substitutions is presented in (18) below.

(18)

Typology of Approximative Allowable Substitutions

- CONSTRUALS
- PERSPECTIVE 1 $\Leftrightarrow$ PERSPECTIVE 2 within the same Event structure. An instance of this type can be *Syntactic coercion* (extending conventional uses or reinterpreting them in terms of novel contexts as in *They laughed* > *They laughed him off the stage*)
- EVENT *figurative* $\Leftrightarrow$ EVENT *literal*
- *Creative* $\Leftrightarrow$ *Formulaic* $\Leftrightarrow$ *Cliché* (retaining the same resemblance structure of objects and relations)
- OBJECT $\rightarrow$ OBJECT
 - from the same conceptual domain:
 1. *hyponymy* = *addition/deletion of meaning*
 2. *granularity* (parallel, increased or decreased)
 3. *metonymy* = *part* $\Leftrightarrow$ *whole*
 - from adjacent conceptual domains (*conceptual clusters*)
- mapping from different domains (*metaphor*)
- (*near*) *synonyms*
- (*near*) *equivalents*
- *word* $\Leftrightarrow$ *definition*
- *word* $\Leftrightarrow$ *examples (list)*
- *prototypes* $\Leftrightarrow$ *peripheries* (an instance of asymmetric skewed alignment)

In discourse sufficiently similar meanings are tolerated for practical reasons – when they bring about more-or-less identical effects even though there is always a construal change (re-conceptualization) in such re-phrasing. The original subjective interpretations are either quite close or fairly distant from the original thought and intentions of the author. In some cases the interlocutors are satisfied with a fairly general level (smaller approximative depth) of communication.

Similarity measures are based on the resemblance criteria with *almost* meanings tolerance thresholds lower (i.e., larger divergencies are tolerated) than in the case for *more-or-less* meanings. A case of an *almost* meaning is exemplified below:

(19)

- There's a particular way you have to make the stroke for it to look good. An aesthetic thing has a certain set, a certain character, which I can't define. Because it couldn't be defined made me think there was nothing to it. But I learned from that experience that there is something to it - and it's a fascination I've had for art ever since.
- Yeah, I see

For the sake of completeness one has to mention the quantitative criteria, which serve as another point of reference in the investigation of the satisfaction values of similarity in

communication and which were discussed elsewhere in the context of translation studies (Lewandowska-Tomaszczyk 2012a). In monolingual contexts the typology of criteria remains identical even though particular approximateness types may adopt different values.

(20)

Typology of communicative (including translational) quantitative criteria

- (i) frequencies of occurrence of lexical units (e.g., synonyms or paraphrases)
- (ii) keyness
- (iii) frequencies of syntactic patterns (complex/simple constructions, sentence types and sentence patterns)
- (iv) frequencies of classes of lexical-semantic patterns
- (v) frequencies of types of figurative extensions (frequencies of Source Domains > Target Domains patterns)
- (vi) quantitative cross-correspondences of concepts from the same conceptual cluster

Consequently, the Common Communicative Platform, expressed in terms of similarity/resemblance criteria or threshold parameters thus form *a multi-peaked radial category space* with a number of *tertia comparationis*, or points of reference, of the qualitative and quantitative types, which serve as conditioning parameters in interaction.

7. CONCEPTUAL DEPARTURES

Allowable conceptual departures in approximative strings, implemented in terms of the major discourse semantic operations, i.e., *lexical* or *conceptual replacement*, *extension* or *addition*, *deletion* or *simplification* are all subject to constraints on sense divergence expressed by a respective tolerance threshold. The boundaries in conceptual divergencies are constrained by similarity between particular linguistic signs in terms of perceptual properties, function, emotional value, aesthetic and ideological judgment. Resemblance is culture-, context- and speaker-specific and as such its variables are not fully predictable outside of context but the original linguistic sign is, to a large extent, a determinant of the size of the possible tolerance spaces with reference to particular attribute values. It is interesting to note that such an operation does not involve exclusively, or even predominantly, language. The first studies inspiring the research on tolerance spaces based on the original ideas of Henri Poincaré as early as 1895 and elaborated by Erik Christopher Zeeman in the seventies (1977), described the work of brain neurons and visual perception and their mathematical modelling.

The central part of a network of senses is, as proposed by Gärdenfors, a standard default (prototype or set of prototypes), which, in interaction, allows for a number of allowable departures. The inventory of departures embraces small or marginal (peripheral, frequently irrelevant) departures, and larger, repairable departures on the one hand and major (irreparable) departures, passing beyond the addressee's tolerance threshold on the other.

To reassume, we can propose the definition of *an allowable departure* from a (default) prototype as a maximum departure that a concept can have and beyond which it may suffer irreparable harm.

The risk involved in crossing of allowable departure threshold (*tolerance threshold*) will result in *critical* functioning of an interaction or interaction damage. The lower bounds on the tolerance areas (lowest allowable departures) can be represented by external (physical) noises, communication channel flaws, etc., while its upper bounds are difficult to determine as they depend on internal reasons, creativity, intentions, affect, dispositions and cannot be predicted but are rather determined locally in context.

7.1. Allowable Departures

7.1.1. Marginal Departures

Small, or marginal, departures may be either considered irrelevant for the purposes of an interaction or can be taken as relevant but not crucial. The discourse signal of a departure of this kind is either not expressed, or is signalled by relevant verbal expressions as in *Not quite – but it doesn't matter* or else the change of the topic e.g., *I didn't quite get it but let's change the topic*.

7.1.2. Reparable Departures

Reparable departures are linguistically expressed as self-corrections, other party repairs, negotiation or taking a compromise. They are signalled by *you-guilty* strategies such as *you got it wrong!*, or an array of stronger disagreement markers (see (20)), *You were not clear about it*, or *I-guilty* tactics, expressed inter alia as *I didn't mean it* or *I wasn't quite clear about it*.

(21)

A: Some people say it's not very good for women to play football

B: That's a lot of rubbish!

A: Well tell me what's good about football for women?

7.2. Irreparable Departures

Irreparable departures lead invariably to a critical communicative state, which finalizes in communication breakdown or boycott as in (21) and (22), or else lead to meta-discursive level, when the interactant identifies a clear absence of a joint (co-operative) communicative intention on the part of the speaker (23):

(22)

That's sheer and utter rubbish. This is a flawed document and indeed it comes to very questionable conclusions.

(23)

Well it's absolute rubbish. I am thinking of doing a little more writing now, but talk of retirement is nonsense.

(24)

A: What is wrong with you!

B: Don't fight with me.

CONCLUSION: AREAS OF APPROXIMATION

The Common Communicative Platform, indispensable if the communication is to be successful, must involve degrees of correspondence between the message sent and the message received, in other words the *degrees of satisfaction of the similarity conditions in communication*. The qualitative and quantitative factors presented (see also Lewandowska-Tomaszczyk 2012a) can secure a resemblance between these different classes of *resemblance* (cf. Lewandowska-Tomaszczyk 2010, 2012).

Approximative spaces are at work in all contexts. Areas of approximation between what we see and how we talk about it are rooted in the diversity of the outside world, language users' perception and their thoughts, expressing their personality, background knowledge as well the cultural and linguistic conventions and constraints (cf. Wilson and Lewandowska-Tomaszczyk 2012 for the dynamicity of emotion concepts), followed unconsciously or with full awareness, as well as in the individual needs and preferences concerning the explicitness of thoughts which surface in an interaction. The communicative act can lead to full (aligned) understanding, can be particularized with respect to the prototypical criteria or can express a *tertium quid*, an indefinite third, at a fairly generalized, non-specific level of communication. Conceptual re-sorting allowed consists in the use of synonymy or paraphrase on lexical and discourse levels, definition, metonymy, metaphor, and the like, and can employ allowable substitutions or repairs, or else can use non-conventional choices, beyond a particular conceptual threshold. While the lower-bound approximative threshold can be crossed due to independent reasons such as external noises or problems with hearing, in other contexts irreparable (upper-bound) departures which take place, lead to communicative fiasco. Similarity, measured as a multivectorial model of distance with respect to a particular reference, or *tertium comparationis*, enables communicative re-conceptualizations, which present degree(s) of conceptual communicative overlap, determined in terms of qualitative and quantitative criteria. Thus, meanings do not seem neatly split between literal and others as inferred from Grice (1961). Neither are they fully subject to contextualization as envisaged by Recanati (2004). Instead, they reside as default networks of senses, activated in context, with multivalued marking, dynamically used within or beyond the conventional tolerance spaces and emerging in interaction.

Chapter 85

WHEN MY EYES ARE ON YOU, DO YOU TOUCH MY EYES? A RECLASSIFICATION OF METAPHORS MAPPING FROM PHYSICAL CONTACT TO PERCEPTION

Karen Sullivan and Wenying Jiang

University of Queensland, Australia

ABSTRACT

Many emotional and cognitive stimuli are perceived through the senses, especially through vision. As a result, metaphors mapping to THINKING or EMOTION often incidentally involve PERCEPTION. This does not mean that PERCEPTION is the target domain of the metaphors. In this paper, we present examples from English and Chinese to argue that the role of PERCEPTION in THINKING and EMOTION has led to the miscategorization of numerous metaphors as synaesthetic, when in fact they map to THINKING or EMOTION rather than PERCEPTION. Furthermore, we suggest that differences between the domains of THINKING and EMOTION lead to the supposed division between “PERCEPTION IS RECEPTION” and “PERCEIVING IS TOUCHING”, and we argue against the grouping of these under the heading of PERCEPTION IS CONTACT between a PERCEIVER and a PERCEIVED (Lakoff 1993). This reclassification has the additional advantage of a stricter and more explanatory delineation of the range of metaphors considered synaesthetic.

Keywords: emotion, sensory modality, synaesthesia, synaesthetic metaphor

1. OVERGENERALIZATION IN PERCEPTION IS CONTACT

The goal of Conceptual Metaphor Theory, like most areas of linguistics, is to seek generalizations that are both consistent with the data and that serve an explanatory function. Overgeneralization defeats both goals, in that it lumps together data that belong elsewhere and fails in explanatory functions such as the production of valid inferences, entailments and predictions about possible examples. For this reason, generalizations should always be

questioned and tested, and if necessary, rejected in favour of more explanatory and better-fitting models.

We suggest in this paper that certain metaphors mapping from tactile contact to visual perception do not stand up to rigorous examination, and we propose alternate explanations for the linguistic examples attributed to these metaphors. The metaphors we will argue against include PERCEPTION IS RECEPTION (as in *The view blew me away*), PERCEIVING IS TOUCHING (*My eyes picked out every detail of the pattern*), and the more general metaphor that purportedly connects these two, PERCEPTION IS CONTACT BETWEEN PERCEIVER AND PERCEIVED (hereafter called “PERCEPTION IS CONTACT”; all metaphors discussed in Lakoff 1993). We re-examine the range of examples attributed to PERCEPTION IS CONTACT, and conclude that only a few of Lakoff’s examples in fact map to PERCEPTION, and that these map neither a PERCEIVER nor a PERCEIVED. Instead, these metaphors follow other synaesthetic metaphors in mapping only a scale of qualities (Petersen et al. 2008). As such, we see no reason to posit a special metaphor distinct from other synaesthetic metaphors to account for these examples. Thus, reclassifying these metaphors allows for a more universal and better delineated definition of synaesthetic metaphor.

We argue that all other examples of “PERCEPTION IS CONTACT” can be attributed to metaphors that involve either cognition or emotion: EMOTIONS ARE PHYSICAL FORCES, PAIN IS PHYSICAL INJURY and THINKING IS MOVING/THINKING IS OBJECT MANIPULATION (Lakoff et al. 1991 [with slightly different titles]; Lakoff and Johnson 1999). While these metaphors do not group together all visual or audio metaphors under a single supercategory such as “PERCEPTION IS CONTACT”, we argue that they offer more meaningful generalizations, in that they recognize that the target domain in each case is not specifically PERCEPTION but rather the emotional effect or cognitive intent of the perception.

These generalizations also hold up better cross-linguistically than “PERCEPTION IS CONTACT”, as demonstrated by a comparison of English and Chinese. In general, both languages share associations between perception, emotion, and cognition. Minor differences between the languages fall within the structures predicted by the metaphors we suggest. Occasional major differences, as in EMOTIONS ARE FORCES, reflect differences in the source domain material that is mapped. Even these, however, involve the same domains and the same role of perception in the relevant domains.

In both English and Chinese, then, mappings from CONTACT to PERCEPTION can be categorized as belonging to five different metaphors, each of which we will discuss in turn. To provide the greatest possible consistency and comparability between our various examples, we will use visual instances of perception in our examples throughout this paper. We will note, however, when other sensory modalities are also possible in a given metaphoric usage. In the next section, we look at synaesthetic metaphors such as *a soft red*, which map temperature onto colour, and surface texture onto quality of colour, light or line. These, we argue, are the only metaphors that truly map to PERCEPTION. Since these metaphors have limited mappings, they do not conflict with a definition as either PERCEIVING IS TOUCHING OR PERCEPTION IS RECEPTION – or even PERCEPTION IS CONTACT. However, since these metaphors give no cause to favour classification as any one of the above, we will refer to them simply as synaesthetic metaphors. Separating these synaesthetic metaphors from the other supposed examples of PERCEPTION IS CONTACT simplifies the category of synaesthetic metaphors, and allows for stronger generalizations to be made about this category.

Sections three through six reanalyse the sets of examples that we argue should not be considered synaesthetic metaphor. In sections three and four, we examine THINKING IS MOVING, as in *her eyes fell on the note*, and THINKING IS OBJECT MANIPULATION, as in *she picked out a detail in the pattern*. Both of these, we will argue, necessarily involve mental attention but only optionally involve PERCEPTION.

Section five looks at EMOTIONS ARE PHYSICAL FORCES, which we argue accounts for examples such as Lakoff's *the view blew me away*. In these instances, we suggest that PERCEPTION takes second place to EMOTIONAL EFFECT.

Finally, we will turn to metaphors mapping from PHYSICAL INJURY to perceptual HARM, as in *the hideous colours assaulted his eyes*. These could be attributed to PERCEPTION IS RECEPTION, but this would overlook their connection to other types of non-physical emotional pain, as in *the horrible thought assaulted his mind*.

Overall, we maintain it is not useful to lump all metaphors involving PERCEPTION into one class. Most of these metaphors incidentally involve PERCEPTION, but map directly to cognition (THINKING IS MOVING/OBJECT MANIPULATION) or emotion (EMOTIONS ARE FORCES, HARM IS PHYSICAL INJURY). These observations point to the dangers involved in metaphor classification, and the importance of analysing occurring and non-occurring mappings, comparing languages, and especially looking for explanations in previously identified metaphors rather than proposing new ones on the basis of one or two linguistic examples.

2. MAPPING SYNAESTHETIC SCALES

Some metaphors involve neither emotion nor cognition, but do indeed map directly from TOUCH to other modalities of PERCEPTION. As such, these metaphors can justifiably be termed "synaesthetic" (Williams 1976). Synaesthetic metaphors occur in many different languages (as in the well-known documentation of Indo-European examples in Sweetser 1990). Indeed, there appear to be universal or near-universal tendencies in the direction in which synaesthetic metaphors tend to occur, and there is general agreement that TOUCH is one of the more common source domains (Ullman 1957, Williams 1976, Yu 2003a, Petersen et al. 2008, Shen and Aisenman 2008). However, TOUCH synaesthetic metaphors map a highly limited range of elements, generally limited to scales of TEXTURE, LEVELNESS and TEMPERATURE, all of which we argue have an experiential basis – that is, a range of contexts in which the target and source concepts co-occur, as in the formation of primary metaphors (Grady 1997, Grady and Johnson 1998). We argue that the metaphoric expressions previously attributed to "PERCEPTION IS CONTACT" but more correctly termed synaesthetic demonstrate the limited range of scalar mappings identified elsewhere in synaesthetic metaphors, for instance in the psycholinguistic observations on synaesthetic metaphor of Petersen et al. (2008).

When scales of rough and smooth TEXTURES map to VISION, they map to scales of CONSISTENCY of tone or shade. A shade of red, or even an artificial light, may be *soft* or *harsh*, for example, mapping a TEXTURE onto the VISUAL QUALITY of the colour or light. Scales of LEVELNESS of a physical surface map onto the visual REGULARITY of a colour. An area of colour may be *smooth* or *uneven*, if it covers a surface regularly or irregularly.

These elements also map to other modalities, such as sound. A whisper may be *soft*, a scream *harsh*, whereas a sustained tone may be either *smooth* or *uneven*. Gaps in the mapping

exist – that is, tastes don't seem to generally be *uneven* in English, though they may be *smooth* – and some modalities receive more mappings than others. However, the fact that so much structure is shared between metaphors that map from TOUCH to different modalities does suggest that these are all subcases of a more general synaesthetic metaphor. In this, then, Lakoff (1993) was correct: in these cases, TOUCH can map to “PERCEPTION”, in the sense of mapping from TOUCH to other perceptual modalities.

Metaphors mapping TEXTURE and LEVELNESS to VISION, SOUND, and so forth are based on experiential overlap between the two domains, in the manner of primary metaphors. A smooth surface may have a more “even” colouration than a texturally rough surface, and a soft object may have a “softer” outline than a hard object. Running a stick over a smooth surface may produce a more “even” sound than a rough surface, and hitting a soft object will give off a “softer” sound than hitting a hard object.

In addition to these scales of TEXTURE and LEVELNESS, scales of hot and cold TEMPERATURES map across modalities. These tend to map to VISION and specifically to COLOUR, as in English *cool blue* or *hot pink*, or as in (1)-(2) from Chinese.

1) 蓝色的房间看起来很凉爽。¹

Lan se de fang jian kan qi lai hen liang shuang.

Blue room look very cool.

A blue room looks very cool.

2) 我的车是红色的，看起来很温暖。

Wo de che shi hong se de, kan qi lai hen wen nuan.

My car is red, look very warm.

My car is red and it looks very warm.

The Center of Chinese Linguistics PKU Database (PKU; ccl.pku.edu.cn:8080/ccl_corpus/) confirms the prevalence of these associations in Chinese, returning 44 instances of 冷色 “cold colour” and 71 of 暖色 “warm colour”, all having the senses in (1)-(2). Example (3) from this corpus is particularly explicit:

3) 在人们心目中，红、黄、橙三种颜色是“暖色”，蓝、绿色是“冷色”。

Zai renmen xinmu zhong, hong, huang, cheng san zhong yanse shi “nuan se”, lan lv se shi leng se

At people heart, red, yellow, orange three colour are “warm colour”, blue green are “cold colour”

In people's minds, red, yellow and orange are “warm colours” and blue and green are “cold colours”.

In English and Chinese, then, the “warm” colours are the reds and yellows of heat sources, such as the sun and fire, forming the basis of a scalar mapping from TEMPERATURE

¹ In Chinese examples in this paper, the first line is written in Chinese characters. The second line is the same sentence in *pinyin*, the official Chinese phonetic system used in the People's Republic of China. This is followed by a word-for-word English translation in the third line. The last line in the example provides an idiomatic English translation. The particle *de* indicates possession and follows adjectives.

to COLOUR. These metaphors, like those mapping from TEXTURE and LEVELNESS, are based on the real-world co-occurrence of sensory stimuli.

In each of the examples considered here, a scale is mapped from some aspect of TOUCH onto VISION or another modality. No other structure is mapped; for example, a warm fire or blanket can cause other objects or individuals to become warm, but a “warm” colour does not cause other objects or people to acquire “warmer” colours. Because only a scale is mapped, the distinction between “PERCEPTION IS RECEPTION” and “PERCEIVING IS TOUCHING” is not relevant in these examples. A phrase such as *warm red*, for instance, maps only the warm temperature itself, and does not map either the heat source “touching” one’s eyes or the eyes “touching” the heat source. This observation aligns with other findings about synaesthetic metaphor and the tendency to map scalar concepts, occasionally quality concepts (Petersen et al. 2008), and also helps explain the facility with which different sensory domains are combined in metaphor (Yu 2003a). That is, if basically the same scalar information is available for mapping from various sensory domains, it is logical that two source domains can be easily juxtaposed and mapped to the same target domain.

In terms of Lakoff’s PERCEPTION IS CONTACT, synaesthetic metaphors provide no evidence either for or against generalizing over “PERCEPTION IS RECEPTION” and “PERCEIVING IS TOUCHING” into PERCEPTION IS CONTACT, because the limited mappings in these examples do not make this contrast relevant. Neither do these examples give any indication that this generalization is necessary. An unnecessary generalization, we argue, is an overgeneralization not warranted by the data. Eradicating such an overgeneralization predictably brings other advantages. In this case, the advantages include enabling a stronger statement about the role of scales in synaesthetic metaphor, and the reclassification of the other supposed examples of “PERCEPTION IS CONTACT”. Let us now turn to these remaining examples and the evidence supporting their reanalysis.

3. THINKING IS MOVING

Unlike the synaesthetic metaphors, some metaphors mapping from TOUCH to VISION map a great deal of additional structure beyond simple scales of co-occurring qualities. For example, a complex set of mappings allow us to understand perception in terms of force dynamics and motion between locations. A visual percept can *attract* or *draw* your eye or vision, or suddenly *catch*, *capture*, or *trap* your eyes or gaze. Your eyes can *fall on* a stimulus, in which case you might be unable to *take* your eyes *off* it. We argue that these examples necessarily map to THINKING, rather than PERCEIVING; and that they might more accurately be captured as a special case of the metaphor THINKING IS MOVING.

Note, for example, that in English the eyes always “move” to the viewed object, rather than the reverse (Yu 2004). The distinction is not one of grammar, in that the PERCEIVER may be either the subject or the object:

- 4) Her eyes gravitated towards the scene.
- 5) The scene attracted her gaze.

However, in English, the PERCEIVED never “moves”, as in the following:

- 6) # The scene gravitated to her eye.
- 7) # Her gaze attracted the scene.

In Chinese, as we will see in the following section, the PERCEIVED can “move” to the eye. However, we will argue that this possibility involves a different metaphor, EMOTIONS ARE FORCES.

When a viewer’s eye “moves” to a location via THINKING IS MOVING, it “moves” so that the viewer’s attention and thoughts can be directed at that location. In contrast, PERCEPTION IS CONTACT makes no prediction about whether the PERCEIVER or the PERCEIVED will initiate the CONTACT. In fact, by combining PERCEPTION IS RECEPTION and PERCEIVING IS TOUCHING, PERCEPTION IS CONTACT explicitly includes the possibility of the PERCEIVER as the instigator (in the TOUCHING subcase) or the experiencer (in the RECEPTION subcase). PERCEPTION IS CONTACT fails to explain why the latter of these possibilities is never realized.

We can also see that the above examples involve THINKING rather than PERCEIVING in that no perception need, in fact, be involved in the metaphor. In all of the phrases discussed so far in this section, *gaze* or *eyes* may be replaced with *attention*. A thought may “attract” your attention; your attention can be “on” a mathematical problem; or your mind can “gravitate towards” a solution to a problem.

The same two possibilities exist in Chinese, in which a visual stimulus may “attract” the eye, or a conceptual stimulus may “attract” interest whether or not vision is involved. This is apparent in the following examples from the PKU Database. In (8), the stimulus (ribbons) is visual; in (9), the stimulus (a mathematical problem) is purely conceptual.

- 8) 彩带营造温馨浪漫的气氛，很吸引顾客的眼球。

Cai dai ying zao wen xin lang man de qi fen, hen xi yin gu ke de yan qiu.

Coloured ribbon build warm romantic atmosphere, very attract customer eye ball

Coloured ribbons build a warm and romantic atmosphere, so they easily catch the customer’s eye.

- 9) 这个数学难题曾经吸引了好几代优秀的数学家为之奋斗。

Zhe be shu xue nan ti ceng jing xi yin le hao ji dai you xiu de shu xue jia wei zhi fen dou.

This mathematic problem once attract several generation outstanding mathematician for it fight.

This mathematical problem once attracted several generations of outstanding mathematicians who fought to solve it.

Neither English nor Chinese appears to require that metaphors of this type must involve PERCEIVING. However, some metaphoric phrases involving THINKING IS MOVING do appear to require reference to vision. Rather than ascribe these to a different metaphor, we suggest that these are instances of visual attention that are not possible in other modalities or with non-visual attention. For example, *She ran her eyes over the painting* has no analogue ?*She ran her thoughts over the painting*. However, this may be due to our inability to concentrate on

different aspects of a painting without recourse to vision. Imagined or remembered visual experience appears to be acceptable: *She mentally ran her eyes over the painting* is much more acceptable than *?She ran her thoughts over the painting*. The same can be said for examples such as *Her eyes (mentally) roamed the room*, which is acceptable if she is visualizing the room in her memory, perhaps looking for a clue or detail. These examples, then, can also be attributed to THINKING IS MOVING. This explanation is preferable to PERCEPTION IS CONTACT in that it allows for generalization over examples of cognition that do, or do not, involve perception; as well as accurately predicting that the perceiver's eye or gaze will "move" to and "touch" objects, but that objects will never "move" to or "touch" the gaze.

4. THINKING IS OBJECT MANIPULATION

Just as THINKING IS MOVING can map from MOVING to visual THINKING, the metaphor THINKING IS OBJECT MANIPULATION can map from OBJECT MANIPULATION to visual THINKING. An additional set of metaphors that Lakoff (1993) considers to involve PERCEPTION IS CONTACT can instead be analysed with a subcase of THINKING IS OBJECT MANIPULATION that deals with visual thinking, much as the set described in the previous section could be felicitously re-attributed to THINKING IS MOVING. The OBJECT MANIPULATION is often explicitly indicated, as in the following:

- 10) Her eyes found the clue.
- 11) She undressed him with her eyes.
- 12) Her eyes picked out a detail in the pattern.

As with THINKING IS MOVING, these examples involve mental attention. However, some of the examples necessarily involve vision to greater and lesser degrees. Very often, we "find" answers, clues, and other IDEAS without necessarily using our eyes, as in *She found an idea in the book*. We can also direct our attention to the "manipulation" of ideas, as in *She mentally undressed him*, in which the subject may be imagining the revealed body with visual or non-visual (presumably tactile) thoughts. *Her eyes picked out a detail in the pattern* involves the mapping UNDERSTANDING IS GRASPING. In this case, the UNDERSTANDING is achieved through visual means. As with any UNDERSTANDING, though, the visual comprehension can be conceptualized as GRASPING.

Some examples involve "pursuit" of a visual stimulus, and as such require IDEAS ARE MOVING OBJECTS as well as THINKING IS MOVING. For example, *Her eyes followed him* or *She tracked his progress across the courtyard* are of this type. In English, the eyes "follow" a visual stimulus. In Chinese, however, they are more likely to "chase" a visual stimulus:

- 13) 最吸引人的是女主角，看电影时我的目光总是追随着她。

Zui xi yin ren de shi nǚ zhu jue, kan dianying shi wo de mu guang zong shi zhui sui zhe ta.

Most attractive *de* is female protagonist, see movie time I *de* eye sight always chase her

The female protagonist is the most attractive part. While watching the movie, my eyes were always chasing her.

Examples of this type are abundant in the PKU Database, as in (14)-(15).

14) 他的目光追随着姑娘的身影。

Ta de mu guang zhui sui zhe gu niang de shen ying.

He *de* eye sight chase girl *de* silhouette

His eyes are chasing that girl's silhouette.

15) 孩子们的目光追随麻雀飞翔。

Hai zi men de mu guang zhui sui ma que fei xiang.

Children *de* eye sight chase sparrow fly

The children's eyes are chasing the flying sparrows.

Uses such as (13)-(15) do not seem possible in English. For example, we found no examples of the subject *eyes* with the verb *chase* in the British National Corpus (<http://corpus2.byu.edu/bnc/>). Nonetheless, the English “follow” and Chinese “chase” examples involve the same metaphor. The difference between the languages is in the type of pursuit that is mapped, with the Chinese examples involving a more intent, rapid motion of the eyes in “pursuit” of the visual stimulus. In both languages, the vision and attention are conceptualized as following a stimulus.

In conclusion, visual attention is simply a subtype of attention. Metaphors such as the examples in the previous two sections do not map primarily to PERCEPTION, nor are they instances of PERCEPTION IS CONTACT. Attributing these examples to PERCEPTION IS CONTACT ignores the relation to other examples of THINKING IS MOVING and THINKING IS OBJECT MANIPULATION; the unavailability of mappings in which the PERCEIVED “moves”; and the optional nature of the element of PERCEPTION in most examples. Moreover, this incorrect attribution causes THINKING IS MOVING and THINKING IS OBJECT MANIPULATION to be confusable with the very different synaesthetic metaphors discussed earlier, as well as with EMOTIONS ARE FORCES, which the next section argues is the true metaphor underlying some of Lakoff's other examples of PERCEPTION IS CONTACT.

5. EMOTIONS ARE FORCES

How does the metaphoric structure of Lakoff's *the view knocked me over* differ from that of any other stimulus that “knocks one over”, such as *the realization knocked me over*? To us it seems irrelevant that *the view* is a visual stimulus. The reaction to the view, not the view itself, is mapped. That is, the EMOTION involved in the reaction is understood as a PHYSICAL FORCE via EMOTIONS ARE PHYSICAL FORCES. There is no need to posit a metaphor PERCEPTION IS RECEPTION or PERCEPTION IS CONTACT when PERCEPTION is only incidentally involved in some instances of the metaphor.

Many of the same types of evidence available for THINKING IS MOVING/OBJECT MANIPULATION also apply to EMOTIONS ARE PHYSICAL FORCES. For example, the element of PERCEPTION is optional in these examples. *The view blew me away* can be analysed in the

same way as *The idea blew me away*. One can be *struck by a sight* or *struck by an observation*, and so on.

Whereas THINKING IS MOVING/OBJECT MANIPULATION involves an active PERCEIVER (sections 3 and 4), EMOTIONS ARE PHYSICAL FORCES instead tends to involve a mobile PERCEIVED, and a PERCEIVER who does not “move” towards the PERCEIVED. In fact, in English, the cause of the emotion always “moves towards” the experiencer. Metaphorically, the PHYSICAL FORCE affects the experiencer. Sentences may be active or passive, but the experiencer is always “moved” and never instigates the “movement”:

16) The view blew me away/knocks me over/moved me/touched me.

17) He was struck by the sight.

Sentences such as “I touched the view” or “I struck the sight” are impossible.

In Chinese, however, the eyes do sometimes “reach out and touch” something, thereby bringing about the emotional effect that is conceptualized as a physical force. In the following metaphoric idiom, people see (“touch”) an object and feel emotions as a result. Example (19) is from the PKU Database.

18) 年轻时的照片让人触物兴怀。

Nian qing shi de zhao pian rang ren chu wu xing huai.

Young time *de* photo make people touch object rise emotion

All sorts of feelings can arise when people see photos of their youth.

19) 这张照片使我触景生情，浮想联翩。

Zhe zhang zhao pian shi wo chu jing sheng qing, fu xiang lian pian

This photo make me touch scene rise emotion, thoughts throng

Looking at this photo, I could not help becoming emotional and various thoughts thronged my mind.

In English, one can say *The photo touched me emotionally*, but not *I touched the photo emotionally*. In Chinese, however, one can voluntarily “reach out” and experience emotion as a result. In the above example, the emotional force comes from a physical object. However, this force may be produced by another stimulus, such as a nostalgia-inducing location. Example (21) is from the PKU Database.

20) 这里是她跟前夫住过的地方，来到这儿难免触景生情。

Zhe li shi ta gen qian fu zhu guo de di fang, lai dao zhe er nan mian chu jing sheng qing.

Here is she with front husband live pass *de* place, come arrive here difficult avoid touch scene rise emotion

This is the place she and her ex-husband used to live. Being here she could not help becoming emotional.

21) 来到父亲生活过的地方，兄妹三人睹物思人，触景生情。

Lai dao fu qin sheng huo guo de di fang, xiong mei san ren du wu si ren, chu jing sheng qing.

Come father lived *de* place, three siblings see thing miss person, touch scene rise emotion

The three siblings came to the place where their father once lived. This place reminded them of their father and they became emotional.

It should be noted that these examples are idioms. It is not always possible to “touch” a stimulus and cause oneself to feel an emotion. Nevertheless, it seems meaningful that these idiomatic examples that allow a viewer to “touch” a stimulus involve an emotional effect on the viewer. Within EMOTIONS ARE PHYSICAL FORCES, the self-causation of emotion logically maps to subjecting oneself to a physical force. It is also logical that this PHYSICAL FORCE would be minor – that is, a touch rather than a strike or a blow – since humans are more likely to seek out mild nostalgia rather than a more violent emotion. In English, this mapping is not instantiated in language, and in Chinese, it seems to be peripheral. Nevertheless, its occurrence in Chinese idioms fits the predicted structure based on EMOTIONS ARE PHYSICAL FORCES. There is no explanation in PERCEPTION IS TOUCHING for the involvement of the emotions in these Chinese idioms, and yet this emotional involvement is an expected and necessary part of EMOTIONS ARE PHYSICAL FORCES. This further emphasizes the need to recategorize English examples such as (16)-(17) as involving EMOTIONS ARE PHYSICAL FORCES rather than lumping them under PERCEPTION IS CONTACT.

6. HARM IS PHYSICAL INJURY

Finally, we argue that HARM IS PHYSICAL INJURY, a metaphor related to EMOTIONS ARE PHYSICAL FORCES, accounts for the remaining examples of the supposed PERCEPTION IS CONTACT. Metaphors frequently map physical HARM onto unpleasant experiences in other modalities, such as VISION. For example, a light can be *sharp* or *piercing* in the manner of a sharp object, metaphorically *cutting into*, *assailing* or *assaulting* one’s vision. Similar mappings extend to other sensory domains. For example, audio stimuli can be *piercing* or *sharp*, and a sound can *assail* or *assault* your ears much as a visual one can *assail* or *assault* your eyes. In these cases, not only is the scale of HARM mapped to VISION or SOUND, but the stimulus of the pain is mapped. Additionally, the healing of pain maps to aiding recovery from an unpleasant stimulus, as in sights that are *soothing to the eye* or in the idiom *sight for sore eyes*, meaning a pleasant visual stimulus that helps heal the effects of negative stimuli.

All of these mappings are also present in Chinese, as indicated by the following examples from the PKU Database. For instance, a bright red can “prick” the eye:

22) 她决赛那天，往日熟悉的红色塑胶跑道变得格外刺眼。

Ta jue sai na tian, wang ri shu xi de hong se su jiao pao dao bian de ge wai ci yan.
She final that day, days before familiar *de* red colour synthetic athletics track
become exceptionally prick eye.

On the day of her finals, the formerly familiar red synthetic athletics track became exceptionally eye-pricking to her.

Here, a sharp object maps to the visual stimulus, bright red. The physical act of pricking maps to the perceptual effect of the red; the pricked skin maps to the affected eyes; and the painful stimulus maps to the unpleasant visual sensation. An audio stimulus may be represented with the same mappings:

23) 用小刀刮玻璃的声音真刺耳,让人不舒服。

Yong xiao dao gua bo li de sheng yin zhen ci er, rang ren bu shu fu

Use knife scrape glass de sound really prick ear, make person not comfortable.

The sound of a knife scraping glass is really ear-pricking, causing discomfort.

In this case, the sharp object maps to an audio stimulus, and the affected skin maps to the ears. The metaphor is fundamentally the same for VISION and SOUND, and is fundamentally the same between English and Chinese.

In both languages, the perceptual stimulus does the “touching”. That is, a bright light can “pierce” your eyes but your eyes cannot “pierce” or “impale” themselves on a bright light. The relevant metaphor mapping HARM is, in Lakoff’s terms, only PERCEPTION IS RECEPTION, never PERCEIVING IS TOUCHING. This is not too surprising given our world knowledge of HARM. We rarely inflict pain on ourselves by reaching out to painful stimuli. The “gap” in mappings, then, can be attributed to the lack of source domain structure available to map to other modalities. Mappings from HARM provide no conclusive evidence against PERCEPTION IS CONTACT.

On the other hand, abandoning PERCEPTION IS CONTACT has the advantage of allowing us to group the above examples with the more general metaphor HARM IS PHYSICAL INJURY. If a bright light *hurts my eyes*, it is probably damaging in its painful effect on the retina. However, if a shade of pink *hurts my eyes*, the offence may be more emotional than physical. Assigning examples such as these to a subcase of HARM IS PHYSICAL INJURY admits this possibility. Some UNPLEASANT PERCEPTS may be more psychological, and thus relate more to the general metaphor HARM IS PHYSICAL INJURY; whereas others may be more specific to a given modality, and relate more to the subcase. If UNPLEASANT PERCEPTS ARE PHYSICAL INJURIES is a type of HARM IS PHYSICAL INJURY, then it is unproblematic that some metaphors would be more specific and some more general. All are cases of HARM IS PHYSICAL INJURY and need not be assigned to PERCEPTION IS CONTACT.

CONCLUSION

Overall, we argue that PERCEPTION IS CONTACT is unnecessary. Classifying the examples discussed here as PERCEPTION IS CONTACT both instigates a damaging overgeneralization and misses a number of more useful generalizations. We argue that the true synaesthetic examples attributed to PERCEPTION IS CONTACT should be instead considered alongside other synaesthetic examples, with which they share attributes such as mapped scales of sensory qualities. Most of Lakoff’s examples of the PERCEIVING IS TOUCHING subcase of PERCEPTION

IS CONTACT can instead be attributed to THINKING IS MOVING/OBJECT MANIPULATION, and most of his examples of the PERCEPTION IS RECEPTION subcase can be attributed to EMOTIONS ARE PHYSICAL FORCES. This is because the former involves an active perceiver who is also a THINKER, and the latter involves a perceiver who feels EMOTIONS. Chinese illustrates an exception to the latter case, in which someone may subject themselves to a nostalgic experience. However, even this possibility fits perfectly within the realm of potential mappings of EMOTIONS ARE PHYSICAL FORCES. Reclassifying these examples, then, abolishes the broad generalization PERCEPTION IS CONTACT but paves the way for several other more explanatory generalizations. This suggests that PERCEPTION IS CONTACT is less descriptive, useful and accurate than the more modest generalizations proposed here.

MODELS AND APPROACHES FOR CHARACTERIZING APHASIA: PSYCHOLOGICAL AND EPISTEMOLOGICAL PERSPECTIVES

ABSTRACT

Aphasia is a neurogenic condition while language is not. In the aphasia field, the direction of reasoning should go from brain injury to verbal impairment; the logical implication is one-way. When the logical implication is inverted, the conclusion is false. This principle allows predicting wrong inferences when the reasoning goes in the reverse order. Maybe that was the cause of the impasse suffered on the matter for more than a century and a half. When prospective approaches are not possible, and trying to attenuate the deficits of retrospective ones, then all the patients should undergo the same psychological evaluations. Post-mortem aphasia studies are always retrospective. Curiously, they are still taken as 'definite'. Aphasia patterns have to be discovered independently of their biological basis in order to avoid circularity; besides, any combination of the latent language impairments has to be recognized. New models concerning the relationship between brain and language have emerged. Beyond the novelty of the instrument used for data collection, deep methodological considerations are necessary not only for discovering the dissociations and interactions among neuropsychological functions, but also for studying the consistency among the different approaches, samples and instruments employed. Nowadays, such consistency has been magnified by dissemination. The impetus to reach consensus with psychological events has led to the shocking situation in which an article published in 1984, for example, has been quoted almost 22,000 times by April of 2015 as synonymous with the procedure for demonstrating diagnosis. Considering the guidelines of 2011 for primary progressive aphasia (PPA) that number was almost 800 in just four years. If the conceptual and the

* Corresponding Author Email: nsvigliecca@gmail.com.

operational definitions are confused, the theory gets into an endless loop. Additionally, the use of typical cases seriously restricts progress. Despite significant improvements observed in the psychological methods during the last years, the psychological outcomes are still puzzling. The ‘comprehension-expression’ organization and the ‘semantics-syntax’ one involve two different systems of classification which are not mutually excluding. Unlike the dissociation between comprehension and expression, the dissociation between semantics and syntax is not easy to observe, even using complex linguistic evaluations. Syntax involves relationships among semantic units but, simultaneously, produces a higher-order semantic unit. Researchers evaluate those levels of ‘semantic’ units to differentiate semantics vs. syntax. The methodology is unclear because changing parts involves changing the whole.

Neuropsychology has two parts. If the validity of the psychological outcomes is doubtful, any language neurobiological model will be doubtful.

INITIAL COMMENTS

This is an essay which deals, principally, with some psychological and epistemological issues in the aphasia topic. The article has more questions than answers, which is good news. When there are many questions, there is material to work. In contrast, when something is perfect and ‘definite’ there is nothing to do. Science is perfectible; it needs problems to evolve.

Today, there is so much neurobiological data to process that the core of reasoning tends to be weak. Instead, literature reviews and summaries of hundreds of articles abound. Data from the new technologies along with the demands of overproduction from the current scientific system overwhelm researchers with a lot of information, which is difficult to crystallize in theories. Considering neuropsychological studies in particular, it could be said that, at the moment, there is just one dominant theory for the neurobiological basis of language. The globalization and the international work networks favor consensus and a tendency to fall into absolutisms as a way to compensate, perhaps, for such level of data production. It is as if all the neuropsychological researchers belong to the same laboratory thus leading to share the same theory. Simultaneously, there is a proliferation of concepts, terms, and proposals emerging from other disciplines and interdisciplines (such as the linguistics and its branches, or the neuropsychiatry and its syndrome-specialties) which complicates the panorama.

Concerning some of these concepts and terms, in this work the phonetic-phonological and the pragmatic aspects of communication will not be treated unless otherwise indicated. Although some authors integrate the fields of semantics and pragmatics they will be separated here as much as possible. The concepts of ‘context’ or ‘intentions’ may be used to partially replace the broad scope of pragmatics. Besides, only the most formal aspects of natural verbal languages will be discussed and any linguistic unit, such as a word or a sentence, will be considered a ‘semantic’ unit. Accordingly, a sentence will be defined here as a linguistic (not a grammatical) unit consisting of one¹ or more words that are syntactically ‘and’ semantically linked to produce a complete thought, i.e., if those words are perfectly organized in their syntactic functions (as determiners, nouns, verbs, etc. throughout the sentence) but they do

¹ Sometimes one single word, which apparently lacks of the conventional structure of a sentence, can transmit the meaning of a whole sentence. In the same way, one single sound can transmit the meaning of a whole word.

not produce sentence meaning, then those (empty/ meaningless) words will not form a sentence unit; simultaneously, if the syntactic constructions do not contribute to produce sentence meaning, then those (disorganized) constructions will not form a sentence unit. This was done this way by mainly considering the use (and/ or interpretation) of sentences in experimental settings.

Trying to simplify the presentation and/ or avoid the use of many linguistic terms, to the extent that this is possible, some terms will be fused: The lexical and semantic characteristics will be indistinctly seen as part of the same process, being the lexical aspects included in the semantic ones. The same will be done with the morphological and syntactic characteristics, which will be seen as part of the morphosyntactic process. The present essay attempts to reduce data and names in favor of expressions which involve reasoning, methodology, and inquiring.

This is not a detailed exposition of the models, theories, and approaches that exist for aphasia (and/ or language), but rather a discussion about their underlying method/ epistemology as a whole. The basis for using the terms of semantics and syntax are basically treated with the attempt of stimulating the discussion. A particular viewpoint is all the time present. As well, the value of psychometry in the scope is reconsidered.

INTRODUCTION

The loss (complete or partial) of verbal language as a result of some brain condition with preservation of the primary inputs (like auditory, visual or somatosensory projections) and outputs (like motor projections) can be defined as aphasia.

Sinanović et al., [1] propose a definition which points out the predominantly mixed nature of the condition in its clinical manifestations:

‘Aphasia is a loss or impairment of verbal communication, which occurs as a consequence of brain dysfunction. It manifests as impairment of almost all verbal abilities, e.g., abnormal verbal expression, difficulties in understanding spoken or written language, repetition, naming, reading and writing.’ pp 79.

Regarding primary progressive aphasia (PPA), Mesulam, et al., [2] state:

‘The diagnosis of primary progressive aphasia (PPA) requires the fulfillment of three core criteria. First, the patient should have an aphasic disorder of recent onset as manifested by distortions of word usage or comprehension that cannot be attributed to more elementary motor or perceptual deficits. Second, this language impairment should constitute the most salient neurobehavioural deficit and the chief impediment to the pursuit of customary daily living activities during the initial stages of the illness. Third, the underlying disease should be neurodegenerative and, therefore, progressive.’ pp 1538

In general, and according to the definitions provided as examples, aphasia is understood as a condition secondary to brain impairment. Naturally, this concept does not extend to the communication system defined as ‘language’ which, at any rate, is related to brain enhancement and whose socio-educational genesis is beyond dispute.

Although both aphasia and language are neuropsychological processes, aphasia is a neurogenic (pathological) condition while language is not.

Epistemologically speaking, in the field of aphasia the direction of reasoning should always go from brain injury to verbal impairment since the logical implication is one-way. It is well-known that, when the logical implication is inverted, the conclusion is false. This principle allows predicting wrong inferences when the reasoning goes in the reverse order. Maybe this was the cause of the impasse suffered on the matter for more than a century and a half.

Away from logic, the feasibility with which medical studies can be performed cannot be neglected. When aphasia prospective approaches are not possible, and trying to attenuate the deficits of retrospective ones, then all the patients should undergo the same psychological evaluations.² Post-mortem aphasia studies are always retrospective. Curiously, they are still taken as 'definite' [3], even if the term 'definite' is incompatible with Science [4].

The (prospective) studies of Tyler and other authors, which are shown next, were selected for their careful experimental designs. This situation allows seeing the variables more clearly and beginning the analysis more comfortably.

Tyler et al., [5] carried out a functional neuroimaging study in which patients with left hemisphere damage or healthy participants listened to spoken sentences that either contained a syntactically ambiguous or matched unambiguous phrase. According to sample selection criteria ('Mini-Mental State Examination' or 'Raven's Colored Progressive Matrices')³ none of the patients were cognitively impaired. Regarding the experimental spoken sentences, those authors stated: 'Even though the ambiguous phrases were presented in a neutral context, subjects have preferences for one syntactic interpretation over another, which affect the ease with which ambiguities can be resolved (Rayner and Duffy, 1986)'. This preference situation, which Rayner and Duffy [6] define as lexical ambiguity, was then controlled by the authors through the incorporation, in the experimental design, of the dominant/preferred and subordinate/non-preferred conditions as independent variables. Interestingly, that was the situation which produced brain-functioning differences between patients with left hemisphere damage and healthy participants in the ambiguous phrases. Beyond neurobiological findings, patients were insensitive to those preferences, and that situation was taken (based on other control tasks) as an index of syntactic rather than semantic deficits. This is an example where researchers evaluate two levels of semantic units (the preferred and non-preferred sentences based on the content of a previous clause) to intentionally differentiate syntax from semantics, i.e., rooted in two semantic categories, researchers get to different 'syntactic' categories thus not only assuming that syntax is, in this experimental context, different from semantics but also concluding that it was syntax (and not semantics) which caused the observed deficits. The form of the verb (either 'is' or 'are') was the cue which these authors used to convert an initially semantic context in a syntactic one. The patients recruited in such work showed almost no semantic impairments compared with syntactic ones (0-6% vs. 0-47%, respectively) in a sentence-picture matching test. This result was also used for interpretations.

² It has to be clear that undergoing the same psychological evaluations is different from achieving (or intentionally searching) the same result patterns for all the patients.

³ Raven Matrices and Mini-Mental are not equivalent tests of cognitive performance; besides since the Mini-Mental is a predominantly verbal test, it is sensitive to left hemisphere lesions [9]. It would be interesting to see the correlation between the tests selected to include patients (as dependent variables) and the results of the experiment.

Tyler and Marslen-Wilson [7] had previously observed that syntactic decisions are affected by prior semantic context, and that syntactic processing is not autonomous from semantics; i.e., the syntactic structure of a sentence is computed with reference to its meaning. Marslen-Wilson and Tyler [8] had also observed that ‘lexical, structural (syntactic), and interpretative knowledge sources communicate and interact during processing in an optimally efficient and accurate manner.’

SOME EPISTEMOLOGICAL COMMENTARIES ABOUT SEMANTICS AND SYNTAX: FROM PSYCHOLOGICAL INTERACTION TO NEUROBIOLOGICAL DISSOCIATION

Independently of the works quoted above, it is well-known that when the interaction between two or more factors has been verified, it cannot be concluded that only one of those factors is causing the studied effects. As well, when two or more attributes (factors/ variables) with their corresponding categories and/or levels of assessment are confused, it cannot be inferred that any of those attributes explains the phenomenon under study.

For example, and going well away from the language subject, if chocolate cake mixtures are put into small molds and vanilla cake mixtures are put into large molds, then it cannot be inferred that either the small molds or the chocolate mixtures produce, let’s say, the most attractive cakes. That is so because the effect of chocolate cake mixtures combined with large molds, and the effect of vanilla cake mixtures combined with small molds are missing.⁴ Although the cake needs from both attributes (mixtures and molds) to be produced, the process involved between the initial attributes and their final fusion is not trivial, represents the method, and is also irreversible. In this case, the attributes of cake mixtures and molds are essentially different in their quality, and the two attributes want to be related. So, and in order to be sure of the causes and effects of such relationship, the levels or categories for the mixtures, and the levels or categories for the molds have to be clearly distinguished and combined.⁵ If qualities and levels are confused (without clearly identifying the types of variables and their categories) as in the example of the cakes, it will be impossible to know what it is measured and interpreted.

Going back to the language topic, the fact that a ‘perfect’ sentence activates certain brain areas, whereas an ‘imperfect’ (or more difficult to perceive) sentence activates other brain areas, does not necessarily validate, let’s say, the semantics-syntax neuropsychological model

⁴ Other examples of levels or categories for the mixtures can be: ‘without sugar’, ‘with a little of sugar’, and ‘with a lot of sugar’; whereas, for the molds, they can be: ‘square’, ‘triangle’, and ‘circle’. Maybe one variable only has qualities while the other variable only has levels to be assessed. The problem is not the type of the selected variables (qualitative or quantitative) but the confusion among the categories or levels of their measures. Such confusion tends to obscure the variables’ effects.

⁵ Apart from the researchers, who represent the designers of the method, there are the interviewees who represent the receivers of the final product. If the qualities and levels of the initial attributes and their assessments are not clearly distinguished, the researcher’s viewpoint may be confused with the interviewee’s viewpoint. The problem is that the final product resulting from the interaction between molds and mixtures also has attributes or variables, such as the different shapes and flavors of the cakes. But such assessments have to be differentiated from the assessments of the initial materials, such as the shapes and flavors of the molds and mixtures. On the other hand, it is possible that researchers (or their techniques) are seeing how the interviewees are cutting the cake rather than seeing how the interviewees are appreciating or savoring the cake.

(see below the hegemonic neuropsychological model) because it is not clear if the qualities and levels of the two supposedly assessed attributes have been well distinguished.⁶ Using one polysemantic word in different linguistic contexts is not simple to experimentally distinguish and match, particularly for semantics and syntax, which are two interacting and highly complex psychological functions. Researchers are changing two categories at a time (one part and the whole), for two intricate attributes which, still, may differ in their quality. Even supposing that exactly one single detail was changed for otherwise identical sentences, maybe the studied brain is distinguishing something different from what is interpreted by researchers. For example, maybe the brain is distinguishing different types of ‘semantic structures’ (such as the meaning of the sentence as a whole versus the meanings of single words or fragmented sentential subunits) instead of different types of ‘syntactic structures’. Beyond semantics and syntax, maybe the brain is distinguishing the linguistic structure which is more attractive, consolidated, usual, easy to decipher, and/ or singular than the other.

Syntax involves relationships among semantic units but, simultaneously, produces a higher-order semantic unit. Interestingly, some researchers evaluate those levels of ‘semantic’ units (e.g., words or sentences) to differentiate semantics vs. syntax, being the sentence level reserved for syntax.

When the method is not clear, results can be freely interpreted with the theory at hand. The problem in this scope in particular is that there are many linguistic theories (for reviews see, [10-15]) but very few neurobiological ones [16-18] to interpret neuropsychological issues.

Nowadays, and psychologically speaking, researchers tend to put in the center of experimental analyses to semantic and syntactic processes, with a clear preference towards studying these processes with comprehensive tasks [16-17].⁷ Neurobiologically speaking, and certainly influenced by the theory of the dorsal and ventral streams for language [19] (including its inspirational theory for visual perception [20, see also 21]) the anatomical dorsal and ventral pathways have now become the main neurobiological explanation for semantics and syntax. Curiously, the original work for the dual stream [19] was predominantly based on speech perception and speech production rather than on semantics and syntax. Beyond the current inclusion of pragmatics as a neurobiological subject of interest, and the discovering of new brain centers and pathways for language processing [16-18], the fact is that semantics and syntax are considered essential (and comparable) linguistic categories under this view: Today, the hegemonic neuropsychological model for language is represented by this view.

At this point, some questions can be asked: Has morphosyntax a different quality than semantics? If this is not true (and they have the same quality): Does morphosyntax involve a different level of analysis (either inferior or superior) than semantics? If this is true, and assuming that researchers have to be located in the superior level to analyze the inferior one:

⁶ Although verbal neuropsychological events are so much complex than cakes and molds, the following equivalence can be posed: The contrast between some correct verbal meaning (e.g., the meaning of a word) put into a perfect sentence versus some ambiguous verbal meaning put into an imperfect sentence would be similar to the contrast between chocolate cake mixtures put into small molds versus vanilla cake mixtures put into large molds. The same would apply to some correct/ ordered morphosyntactic construction versus some ambiguous/ disordered morphosyntactic one. The methodology is unclear because, in this case, changing some parts involves changing the whole.

⁷ There is also a preference towards studying the syntactic process, which seems to be clearer than semantics for measuring and interpreting (see below).

Is morphosyntax an inferior level of analysis within semantics? Or is semantics an inferior level of analysis within morphosyntax?

If semantics and syntax differ in their quality, they cannot be compared in the same way that ‘cake mixtures’ and ‘molds’ cannot be compared. They cannot be directly assessed as subsets belonging to the same category and/or be measured by the same yardstick. If some relationship between semantics and syntax wants to be established with reference to another variable, they will need more complex analyses, than those of the cake example, to avoid psychological confusion between qualities and levels.

Maybe semantics (in its broadest sense) is not a level in the hierarchy of verbal language, as are commonly considered the phonetic-phonological and the morphosyntactic ones. Perhaps it is more an attribute which breaks through the levels of other verbal attributes, thus acting all the time as a parallel (or surrounding) process rather than as a sequential one.

Syntax involves the rules for articulation/ linking, which are easy to teach and learn, but the rules for understanding are more difficult to find and transmit. (Perhaps this is due to the fact that syntactic rules are more stable and restricted, while semantic rules are more chaotic and versatile).

Usually, semantics and syntax are seen as complementary processes where semantics would be the content/ the *gnosia*/ the ‘what’ while syntax/ morphosyntax would be the form/ the *praxia*/ the ‘how’ (or where). However, and without forgetting that verbal language is a biosocial instrument developed by human beings to better control and organize communication, the following analogy can be proposed: By considering semantics as the content of ‘water’ and morphosyntax as the human tools or ‘containers’ which gives form to such content, water will not stop being water by taking the shape of the containers that human beings invented to contain, control, organize, and understand it. On the contrary, if the containers disappear when human beings have already become accustomed to the containers, the water will slip through their fingers and an important part of human beings will be lost, i.e., as human beings can no longer manipulate water, they will enter into crisis.⁸ The analogy is used to show not only the importance of tools for humans, but also (and for didactic issues) the relative importance that contents and containers may have in certain contexts.

Considering morphosyntax just as a tool, semantics would not only represent the content ‘poured into/ passed through’ the morphosyntactic structure but also ‘the root and the goal’ of the process mediated by syntactic sequencing. Surrounded by this wide-ranging structure or matrix, morphosyntax would be an inferior level of analysis within semantics. As it will be seen below, this perspective is apparently difficult to conceive or understand by the hegemonic neuropsychological model for language. Such misunderstanding may lead to interpret results in the most convenient way or, most probably, in the easiest way to be carried out or decoded. Such way is usually the linear and analytic one. The problem is that interpretations generate theories.

The attempt of analyzing the complex interactions between semantics and syntax by taking into account just one epistemological point of view (e.g., the linear or the nonlinear

⁸ Usually, when human beings become accustomed to a new tool, it is difficult to go back to an old one. This can lead to confound the adjectives of ‘new’, ‘later’, or even ‘human’, with ‘better’ or ‘superior’. Taking into account the specific context in which scientists have to work, the experimental method is also a human (logical) tool, necessary in scientific settings, but it cannot be compared with the old, wild, and wise intuition, which human beings are progressively losing. Maybe syntax is closer to the experimental method (thus favoring syntax study) while semantics is closer to intuition.

one) may lead to a reductionism which can detract the whole process of verbal processing in any direction. Returning to the example of the contents and containers, the attempt of reducing the complexity of semantics to simplistic (linear and partial) syntactic analyses would be equivalent to try to understand the essence of a cake by seeing the details of the mold. The analysis in the opposite direction can be proposed as follows: the attempt of expanding/ observing the particularities of syntactic analysis through a more comprehensive semantic view would be equivalent to try to understand the details of the molds by seeing all the ingredients of the cake mixtures. Although both expressions are strange, the second is not so unrealistic in the sense that a mold has turned out a useful instrument, created to improve the presentation of the cake, but not vice versa.

Catani and Bambini [16] propose a theoretical model for analyzing social communication and language in which five levels are hierarchically and serially organized according to developmental and evolutionary aspects. When describing the level 3, which is the 'anterior temporal networks for lexical and semantic processing', the authors state: '...the temporal cortex is involved in selecting verbal labels for objects in a posterior–anterior progression of word comprehension, from generic to specific levels of precision.' When describing the level 4, which is the 'fronto-temporal network for syntactic analysis', for some reason the authors intentionally use the term 'analysis'. Although they say that the Wernicke's region participates in syntactic analysis, they do not specify a certain direction for either the progression or the level of precision as they did for the level 3. They affirm: 'successful syntactic processing requires the interplay between lexical properties and syntactic analysis, which is mediated by the joint activation of the whole frontotemporal system connected through the long segment of the arcuate fasciculus.'

It is not clear whether the term 'syntactic analysis' was used by Catani and Bambini [16] as synonymous with 'syntactic processing' or if it was used as a singular way of conceiving (or studying) the particularities of syntactic processing. Besides, at first sight, both processes seem to be analytic. If that is so, not only the semantic processing would go from something more generic to something more specific but also the syntactic processing.

To understand the model of Catani and Bambini [16] some alternative appreciations can be formulated concerning semantics and syntax. While continuing the discussion of the differences and interactions between those two functions, conciliations among terms or concepts will be searched.

Compared with syntax, maybe semantics is a more complex process that surely exceeds verbal language and human scope, as well as partial and linear analyses; it is probably more related to the principles of holistic perception or even to the gestalt theory, and it cannot be understood outside its context or background, at all ages. In the attempt to find a schematic representation for this process, semantics could imaginatively be seen as a network of meaningful contents or symbols, which mostly are intersecting with each other; some may be closer to others, some may be stronger than others, and some may be isolated from others. The patterns of their relationships would be dynamically determined, among other reasons, according to the standards, points of view, needs, and the significance for survival of the people involved in communication. Those patterns not only would be transversally affected by human interaction, at the very moment of communication, but also longitudinally, throughout each step of the development. Considering that verbal labels are human conventions established for certain meanings, the association between the original network of nonverbal contents and the verbal construction of linked labels is probably the main

characteristic of semantic integration. Therefore, the convergences and divergences between phonological and morphosyntactic features will also affect the patterns of semantic relationships.

If all the possible linked labels are visualized as a nonlinear surface, and a sentence as a curve line, a dynamic interaction can be conceived where the movements around a certain meaning, or the constructions around a certain sentence, will have more or less significance. Accordingly, the movements and constructions will act at different moments (initially, subsequently, or simultaneously) depending on the context. Movements, constructions, and moments are linguistic associations acting in a certain context. But if only one association is considered the most significant, and the other associations are considered just pieces of the first association, there will be an oversimplification of the whole process. For current neurobiological theories, syntax seems to excel semantics as a superior level: as a more abstract representation, higher-order function, and later-in-time stage. However, it is highly probable that both linguistic functions require complementary forces interacting with each other, as part of the same process. Considering the history of linguistic knowledge, it is difficult to explain why the isolated line of a sentence (just a handful of linked labels) became more important than its surrounding matrix. Maybe that was so because the final expression of verbal language follows a linear arrangement, which is a necessary (but not sufficient) characteristic in this type of communication.

Bearing in mind the need of interaction between semantics and syntax, it can be observed that sometimes 'pure' thoughts go faster than words, thus producing incorrect utterances. However, when the semantic associations are harmonious with the morphosyntactic ones, utterances will go out correctly aligned. In order to convert 'pure' thoughts in 'verbal' thoughts and, then, in explicit utterances, everything that takes place simultaneously and involving many areas and functions of the brain (such as attention, perception, gnosis, praxis, memory, associations of any type, social-emotional adjustment, global cognition, and so on) at some point has to follow the linear mode of verbal language.⁹ Some of the associations that the brain can do to semantically organize an utterance can be deduced from the nature of the errors committed during spontaneous speech: The presence of paraphasias of any type, the inopportune influence of emotional sources, as well as the previous and subsequent thoughts, which can be jumbled up with the current expression, are frequent examples of these associations.¹⁰

When the syntactic analysis of a sentence is defined as a sort of a formal reasoning, maybe such reasoning is conceived like a sequence of (empty) compartments useful to organize the world of word labels, which would follow a similar organization to the world of nonverbal representations.

Verbal ability requires that all that internal universe of feelings and ideas finally goes out aligned and synthesized for that narrow channel of morphosyntactic 'molds'. In that channel, every part of every linguistic unit has to be assembled with the next in order to be converted

⁹ When thoughts go out correctly aligned through the final verbal and linear mode, it is not difficult to imagine the similarity with different containers passing through an assembly line, in which the different contents are correctly placed in their specific containers.

¹⁰ Probably this kind of errors affects communication more seriously than the 'purely syntactic ones' (see below). To what extent such more serious semantic errors are produced because the syntactic compartments have been seriously broken is an open question.

in a meaningful and well-organized expression.¹¹ Maybe for this reason expression (speech production) is sometimes confused with syntax. However, comprehension (speech perception) also requires that the received message pass through that narrow channel: All the received contents must be correctly placed in their specific morphosyntactic ‘molds’ so that the receptor’s brain could deal with a well-organized/ decodable verbal unit; i.e., all the words and/ or sounds of the message have to be ordered in such a linear mode because, otherwise, the message will not be perceived as a verbal one. Afterwards, the verbal message would semantically spread to the whole brain thus reaching the different networks of memory and cognition for a whole and multimodal interpretation.

Semantics would be dynamically guided by an advanced organization established during the phylogeny and ontogeny that resembles the process of perception: A top-down perspective which goes from generic to specific levels of precision (see Catani and Bambini, [16]) would be dominant. Under this organization, it is necessary to first recognize the general meaning (the whole background) to then analyze/ select a specific meaning or detail.

Taking into account some of the variables usually studied in the laboratory, the linguistic preferences [5], levels of difficulty, and frequencies of use, which by the way are all interconnected, are probably more related to semantics than to syntax.

Within the cultural factors associated to both linguistic processes, morphosyntactic knowledge would be more compulsorily taught, and more sociologically and logically organized, while semantic knowledge would be more intuitively perceived and more automatically and biologically organized, to a certain extent. Usually, it is easier to show or share semantics than to explain it. Maybe for this reason it is more difficult for neurobiological researchers to operationalize and analyze semantics components than syntactic ones. Probably, the more human is an attribute, the easier is to analyze it. Reciprocally (and paradoxically for humans), the more primitive is an attribute, the easier is to integrate and perceive it. The semantic ability involved in extracting the figure (the most relevant meaning) from a background of competing linguistic stimuli, according to internal and external demands, is dynamically and progressively constructed along with the rest of the cognitive abilities. With time, and living in a coherent world, human beings will learn to prefer the meaningful stimuli and reject the meaningless ones according to: their frequency and quality of appearance, consistency to reward, usefulness to find biological or social solutions, pertinence for a certain situation, etc. Verbal stimuli are not the exception.

To have an idea of the complexity of semantic processing even using single-word tasks, or just two prepositions, see Wright, et al., [22] as well as Marslen-Wilson and Tyler [8] for an experimental approach which uses picture naming and word–picture matching; see also Kelleher and van Genabith [23], for a computational model which uses two prepositions and shows nonlinear images.

When sentence semantic processing wants to be assessed in functional neuroimaging studies, a common way that researchers use to produce a modification which affects the meaning of a sentence (without changing syntax) is to change a single word in the sentence. This procedure is enough to reach the desired effect with clear experimental conditions: Changing several words, using implausible sentences or series of unconnected words, involve more variables and complicate interpretations. But changing just one single word (with high

¹¹ ‘There is a lack of consensus on the nature of the process of linking; that is, how the conceptual form of thoughts determines the form of the spoken expressions used to describe them’ [15].

linguistic weight) may be semantically equivalent to change the entire sentence. Considering an example of Newman, et al., [24] (also quoted by Hagoort and Indefrey, [17] and by Murphy [15]): ‘my mother ironed a kiss’; the misuse (unusual presentation) of a single word changes the meaning of the whole sentence. Since the highest semantic level of the sentence unit is dominant, all the lower-level semantic units will cooperate to form the biggest conceptual representation (or the most relevant perception), no matter if the generated image/meaning is usual or unusual. So, it is highly probable that, for the receptor's brain, ‘the meaning of each linguistic unit and the global meaning of the sentence are determined simultaneously’ [25].¹²

On the contrary, the change of a single morphosyntactic sub-unit or detail does not change that easily the perception of the whole meaning of the sentence. Actually, it can be observed that, in the spontaneous/ colloquial speech of healthy people, a lot of morphosyntactic errors are committed without affecting communication. By using the same example quoted above, the change of the word ‘ironed’ by ‘give’ instead of ‘gave’ or ‘gives’ (i.e., ‘my mother give a kiss’) maintains the meaning of the new sentence in general terms. By using another example with a more serious error like ‘the park was placed on the statue’ (an inversion error which can be mediated by semantic or syntactic reasons) listeners will still understand the entire meaning of the sentence. That is so because listeners correct the unfeasible/ funny detail thus maintaining the balance between the whole and the parts [26]. When this balance in the sentence is broken, and the whole meaning succumbs to the parts, the sentence becomes fragmented: Verbal language disintegration occurs when the context, the subjective and objective cues, as well as the communication efforts made by the involved persons are useless.¹³

Beyond specific cases of verbal language fragmentation, researchers try to maintain the balance between the whole and the parts by modifying just a semantic or syntactic detail in the experimental condition and leaving constant the rest. In this attempt, and beyond the interaction between semantics and syntax, researchers also involve the interaction between analysis and synthesis, which is dependent of age and education among other factors. Complex tasks involving these four functions are better accomplished from teenage years onwards. Complementary cognitive requirements such as divided attention, mental tracking, attention span, working memory, and executive functions may be necessary for these tasks. For example, it is well-known that if an analytic task wants to be carried out, the interviewee first has to have an idea of what is going to be divided. So, if the background of the biggest stimulus cannot be preserved by any cause, the analytic task will be impossible to be carried out. These developmental aspects are not ignored by researchers.

Complex syntactic analyses are acquired later in the development. Furthermore, when this learning is incipient, it is probable that the more conscious and broken is the syntactic analysis, the more difficult is its intuitive perception: Children probably have to inhibit synthesis or integration in order to analyze. Later, they will automatically complement analysis and synthesis and use them together thus organizing harmonically the sub-units

¹² Unlike the semantic processing of a sentence, the syntactic processing probably involves that each linguistic subunit and the global syntactic structure are determined consecutively, particularly in experimental contexts (see below).

¹³ When the language fragmentation goes beyond a single sentence or moment, and affects the entire verbal language, it is time to analyze the type and level of distortion in order to determine the type and level of aphasia.

within the biggest unit. Correctness (culture) also depends on the level of education, which is not a minor detail in the neurobiology of language.

Nonverbal processing comes first in the evolution [27, 28], then the verbal-auditory one, and then the verbal-visual one. Concurrently, and as it is reported by Catani and Bambini [16], semantic processing would come first than syntactic analysis. The last acquisitions are the most culturally biased [29] and, usually, the less cognitively crystallized. Brauer, et al., [30], observed that seven-year-old children possess a brain connectivity pattern of the dorsal language route that is similar to the one observed for adults. Those authors affirm: 'It is at around this age that children start to successfully process more complex and also passive sentence structures' It is also hypothesized that seven-year-old children do not have yet the ability to process complex sentence structures (as may be processed by adults) since the dorsal pathway is still not yet fully mature. Brauer, et al., [30] also leave open the question about how the connection between neural and syntactic developments actually occurs. In any case, the ability to consciously disentangle the components and rules of syntax in a sentence is a late acquisition.

If syntax was developed to favor the organization and sense of communication (i.e., if the main point of the sentence compartmentalization and word sequencing is to transmit information with meaning) maybe the most important syntactic components are those which are more prone to affect the highest-order meaning. In the erroneous example quoted above (i.e., 'my mother give a kiss') the syntactic distortion does not change the meaning of the sentence because, probably, this is a minor detail for communication. To a certain extent it seems that evolution (unlike some researchers) prioritizes meaning over specific details of form and syntax. When morphosyntactic rules are momentarily broken, semantics becomes dominant in order to protect communication: Given a certain conversation in which the speaker cannot articulate sounds or words for an instant, it is common that the speaker claims: "You know what I'm saying;" and it is also common that the listener pay attention to what the speaker wants to say as well as to what he/ she as a listener wants to listen in order to not to interrupt the feedback.

When morphosyntactic resources are at risk, semantic units of any size cannot be constructed or correctly linked with other units. But when semantic resources are at risk, the morphosyntactic resources lose their reason for being; therefore, communication in itself is at risk. However, and contrasting with other types of language, 'pure' verbal language requires from the interaction between semantics and syntax.

Unlike semantics, the syntactic processing described by Catani and Bambini [16] as 'syntactic analysis' is probably more related to the principles of an analytic approach for understanding (or perceiving). Under this perspective, maybe a sentence is conceived as a linear arrangement easily dissectible throughout several compartments, from the beginning to the end of the linguistic unit. When the direct comprehension of a sentence from the beginning to the end (or from the left to the right in the case of reading) is experimentally hampered by a linear configurational complication, such complication is usually defined as a syntactic manipulation in neurobiological research settings. Under the influence of such complication, the sentence linear arrangement has to be altered in its standard form of being perceived (including loops and prolongations), or in its natural way of being explored

(including interruptions and comebacks) so that the comprehension task (i.e., the cognitive synthesis or semantic integration) can finally be achieved.¹⁴

When the syntactic processing is neurobiologically evaluated, there are at least two sentences to be compared being one of them simpler (to be constructed or understood) than the other.¹⁵ When syntactic comprehension and expression are evaluated, researchers may force interviewees to pay attention, for example, to the analysis of the form in which the interviewer is expressing the sentence. By this means, researchers (rather than interviewees) are sometimes putting syntax as figure and semantics as ground.¹⁶ Perhaps the ability to bring awareness to certain unconscious processes (which at the moment of the evaluation are already automatically made) is easier for syntactic than for semantic integration tasks.

Apparently, syntactic manipulations have had positive results for neurobiological findings.

Hagoort and Indefrey [17] observe that sentences containing a subject -relative clause (e.g., “The reporter who attacked the senator admitted the error”) are found to be easier to understand than sentences with an object -relative clause (e.g., “The reporter who the senator attacked admitted the error”). On the one hand, these authors highlight the integration between semantics and syntax and some subtle questions concerning the impossibility of studying both processes as separated ones are suggested in the introduction of their work. These authors affirm that the degree of separation between networks for syntactic and semantic integration is not so clear:

“Separation of these networks is nontrivial because syntactic differences are not without semantic consequences...A difference in syntactic structure clearly has immediate consequences for mapping grammatical roles (subject, object) onto thematic roles (agent, undergoer) and hence for the...conceptual/ semantic representation of the sentence” pp 350.

On the other hand, these authors attempt to segregate the two types of processes as much as possible using data from a meta-analysis of numerous functional imaging studies. With this vision in mind, they follow their dissertation writing a subtitle where the syntactic processing is put against the semantic one, and begin such section with this sentence: ‘So far, the available information is most clear for the areas involved in syntactic analysis’.

It is beyond any dispute that fertile information can be obtained from the use of some syntactic-analytic paradigms. For example, some interesting effects can be discovered by restricting the syntactic analysis just to comprehension (listening or reading), and by

¹⁴ From a simplistic point of view, and excluding complex interactions among semantics, syntax, analysis, and synthesis (see above), it could be said that, overall, when morphosyntactic processing is involved in expression, a top-down arrangement would be dominant; on the contrary when morphosyntactic processing is involved in comprehension, a bottom-up arrangement would be dominant. When the research involves healthy adults and complex syntactic analyses, bottom-up and top-down perspectives will interact.

¹⁵ If math performance is compared to syntactic performance, the operations of 3+3 and 18/3 produce the same result, which might be considered the final meaning, but both operations differ in quality and complexity. Both operations also have their own meanings and labels.

¹⁶ The 10-item version of the Northwestern Anagram Test, used by Catani et al. [31] which measures object- and subject-extracted ‘who’ questions (e.g. Who is the groom carrying?, Who is carrying the bride?, respectively) apparently is an example. In this test of grammatical processing, which has to be answered with visual stimuli, the patient is asked to order single words, each printed on a separate card, to correctly depict the action in a target picture.

assuming that, before integrating the sentence components as a whole, interviewees can sequentially detect the complication, i.e., interviewees can pay attention to the ambiguity, the error, the difficulty, the object or subject used in a certain order, the verb used in a certain form, etc. when such complications appear in the line of the sentence. Within this framework, Malaia and Newman [32] carried out an EEG study in which they analyzed the topographical distribution of alpha power to identify the time course of the linguistic binding process during word-by-word sentence reading. By manipulating semantic information (e.g., noun animacy) and syntactically-relevant information (e.g., verbal template), these authors demonstrated ‘that the processing of semantic and syntactic features during sentence comprehension proceeds in highly integrated fashion using gating of attentional resources to facilitate rapid comprehension, with attentional suppression of global alpha power to facilitate interaction of local networks.’

At the present time, there are few studies which escape from the hegemonic position and, thus, few authors who demonstrate a neurobiological interaction rather than dissociation between semantics and syntax. Besides, and by following the new trend, it is generally assumed that semantics is an inferior level of analysis within morphosyntax: Changes in syntactic structures would not affect semantics or, if so, they can still be considered pure syntactic changes. Under this analytic/ syntactic-dominant view, semantics would apparently be represented by the elementary or lower-level units useful to construct the bigger structure of ‘syntax’ (not the bigger structure of semantics).

Hagoort and Indefrey [17] affirm that syntactic integration cannot simply be reduced to semantic one. So, and based on neurobiological findings, this trend would include the more basic semantic elements (usually single words or simpler-than-sentence semantic units) within wide-ranging syntactic operations. From this perspective two expressions can be syntactically matched even if they are semantically empty (see, e.g., [5, 8]) but not vice versa. Under this view, syntax is considered superior to semantics, which serves to build syntax.¹⁷

LINGUISTIC MANIPULATIONS AND CONCEPTS: NEUROPSYCHOLOGICAL USES AND INTERPRETATIONS

Disordering or changing the words of a sentence is effortless in view of its linear characteristics; the question is how the interviewee will semantically perceive those changes. Without the researchers’ interventions, it is usual that the interviewee’s brain correct the input distortions to a great extent. Let’s take the following example with five specific words (‘car’, ‘speedy’, ‘the’, ‘is’, and ‘red’), used with an unusual syntactic structure: article + adjective + adjective + verb + noun. Then (and obviously presented in a methodologically reliable context) ¹⁸ it could be possible that a rare expression like ‘the red speedy is car’ is neurobiologically perceived by the interviewee as a more common sentence like ‘the red car is speedy’ or ‘the speedy car is red’. Thus, the interviewee would be semantically matching

¹⁷ Under this view, the content (e.g., the cake mixture) has turned out useful to improve the presentation of the mold or, worse, the content has turned out to be just as an accessory that can be used or not.

¹⁸ If the expression ‘the red speedy is: car’ is applied in a context where the interviewees have to guess what moves at high speed, the example will not be relevant. By the way this (personal) semantic association shows how the brain is always looking for a meaning where an unusual expression can fit: A visual image appears, for an unusual expression.

(perceptively correcting) the rare expression with a more frequent one. Outside the laboratory, this is a common situation in particular if the wrong sentence is quickly said within a correct linguistic background or context. Even inside the laboratory, the experimental context in which a distortion (or peculiarity) is included is also important: If one unusual sentence is included within a context of usual series of sentences, the change will be easily detected. The balance between usual and unusual conditions is an intervening variable. At once, if one distorted word with low semantic or syntactic weight in the sentence is included within a context of words with high linguistic weight, the change will be uneasily detected. If this is not so, at least it would be worth studying at what time the experimentally manipulated 'sentences' begin to be neurobiologically perceived as fragmented sentences, isolated phrases, or series of words. On the other hand, if semantics wants to be excluded (or preserved constant) from a syntactic experiment, ideally the stimuli to be compared should be equally easy to understand.¹⁹ Besides, in the paradigms that compare sentential conditions in common with non-sentential/ asyntactic ones, these conditions should match in semantics as much as possible, in particular if they are used for making semantic inferences. However, all these control conditions taken together are very difficult to achieve.

In fact, and based on the neurobiological consequences of the current hegemonic theory, it does not matter if semantics and syntax differ in quality or not; they can actually be compared, measured by the same yardstick, and put in the same line of methodological and linguistic analysis. If there is some kind of interaction in their psychological/ initial factors, they finally get dissociated to the searched endpoint. May be this is a case where the end justifies the means because, by these means, researchers have found the neurobiological differences they were looking for. Following this way of thinking it could be said that, at the present time, behavior appears as a sort of 'black box' within the manipulable inputs and dissociable outputs of neurobiological experiments. That is so, even when the inputs in themselves are confused and, also, part of the 'behavioral black box'. Besides, it is difficult to understand that clear outputs can emerge from confused inputs. Hagoort and Indefrey [17] observed, for example, that Brodmann area (BA) 44 activation is clearly driven more strongly by syntactic than by semantic demands, suggesting that this region contains neuronal populations involved in syntactic operations *per se* or that the semantic consequences of such syntactic demands (e.g., difficulty of thematic role assignment) are processed by neuronal populations that differ from those processing other kinds of semantic consequences.²⁰ This

¹⁹ The use of active and passive voice, e.g., is considered a classical paradigm for assessing syntactic processing [5]. However, the level of difficulty and the frequency of use of the two sentences are not matched; passive voice is acquired later and is more difficult to be constructed and understood than active voice. So, not only two levels of syntactic functioning (and two stages of verbal development) are compared, but also two types of semantic units. As said above, researchers are changing two categories at a time for assessing one attribute which includes the other.

²⁰ Hagoort and Indefrey [17] also observed a distinctive activation pattern in the posterior left inferior frontal gyrus (LIFG): Syntactic demands activated more dorsal parts (BA 44/45) and semantic demands activated more ventral parts (BA 45/47) across all kinds of increased processing demands (violations, ambiguity, complexity) and in studies performing direct comparisons of high syntactic and semantic processing demands. Additionally, the dorsal/ventral gradient observed in the LIFG seems to be mirrored in the left posterior temporal lobe. Alternatively, Catani and Bambini [16] propose that the fronto-temporal networks for syntactic analysis are associated with the long segment of the arcuate fasciculus (the dorsal network) while the anterior temporal networks for lexical and semantic processing are associated with the middle and inferior longitudinal fasciculus, the uncinate fasciculus, and with the extreme capsule/inferior fronto-occipital fasciculus (the ventral networks). Both teams found dorsal-ventral dissociations for syntactic-semantic operations, respectively, in agreement with the anatomical proposal of Hickok & Poeppel [19].

statement leaves open the possibility for other interpretations (more integrative ones) regarding the relevance of semantics compared with syntax. For example, that semantics can only be ‘affected’ by syntax in the same way that can be affected by many other verbal (and nonverbal) factors or, maybe, that ‘semantic integration cannot simply be reduced to syntactic integration’ (see above the opposite affirmation expressed by Hagoort and Indefrey, [17]).²¹ Almost certainly, verbal integration cannot be reduced to just these two psychological functions, whatever are their natures or levels in the hierarchy of language.

Semantics and syntax can be considered verbal organizers with different rules of organization. Semantics and syntax supposedly represent useful processes to sort, dissociate, and combine words within a linguistic context. It is generally accepted that sorting words by their relationship with the objects in the world involves a semantically driven process, while sorting words by their relationship with other words in the sentence involves a syntactically driven one. But there is also a world of words, in which every label and group of linked labels not only have their own meanings, but also generate new meanings when they are dissociated or combined. Researchers are trying to elucidate this organization and its rules. However, the hierarchy which organizes the different levels (or categories) of these linguistic processes is still today difficult to validate. I.e., the art of combining elements is cognitively superior to the elements themselves, the problem is that, for verbal language, there is much debate about the art and the elements. Such art is these days interpreted as syntax. However, the combination of elements arises from (and is addressed for) something, which gives sense to the whole creative process. The ability to give sense is semantics. Most probably, multiple psychological functions and sub-functions (including semantics and syntax) are acting together for verbal integration thus involving many connections in many directions in the brain. For example, the generation and preservation of the highest levels of cognition supposedly facilitate the processing of the lowest ones but, for that, the lowest ones have to exist [26]. However, the current (widespread) neuropsychological techniques have not yet transferred such hierarchical integration to statistically based theoretical frameworks.

‘The notion of bio-physiological dimensions for verbal language (and aphasia) involves the notion of neuropsychological functions and the need of validation... It is a common expression to say that a test measures certain neuropsychological functions. Yet, those functions are concepts which need to be empirically validated...The constructs of verbal comprehension and verbal expression are among the most widely used in literature ...Impairments in such domains may be related to comprehensive and expressive aphasias’ [29].

Considering some of the most used neuropsychological constructs in the scope, it is worth noting that semantics and syntax are more abstract concepts than comprehension and expression, which involve a more direct link between their conceptual and empirical definitions. Semantics and syntax, on the other hand, need further studies on the interaction with other verbal and cognitive constructs. The study of the interaction between the semantics-syntax system and other functions such as speech, repetition, naming, reading,

²¹ Actually, the exact words of Hagoort and Indefrey [17]) were: ‘syntactic unification cannot simply be reduced to semantic unification.’ The term ‘unification’ is used by these authors to indicate the real-time assembly of the pieces retrieved from memory into larger structures, with contributions from context.

writing, phonemic processing, attention, memory, and praxia, among other functions, is essential for both language and aphasia.

Within the field of aphasia, and by using the categories of nonfluent/agrammatic, semantic, and logopenic aphasias, the guidelines proposed for the PPA variants [3] rely more on the semantics-syntax organization than on the comprehension-expression one. Recent empirical studies on the matter [33], however, tend to dichotomize the PPA outcomes towards the classical difference between fluent and nonfluent aphasias, instead of the three variants initially proposed by the guidelines of 2011 [3].

Before continuing, it would be suitable to clarify certain points: As said before, the dorsal-ventral dissociations described, respectively, for syntactic-semantic operations [16, 17] as a general rule agreed with the anatomical proposal of Hickok and Poeppel [19]. However, this last model tried to integrate different theoretical views, types of tasks, methodological approaches, as well as different samples, including patients and healthy participants. Moreover, Hickok and Poeppel [19] predominantly reviewed the auditory and motor representations of speech, explicitly, the processes of speech perception and speech production whereas Catani and Bambini [16] and Hagoort and Indefrey [17] predominantly reviewed verbal comprehension in healthy participants. Speech production was rather avoided in these last two models.²²

Regarding the present work, ‘verbal perception and verbal production’ will be seen as equivalent to ‘verbal comprehension and verbal expression’. At once, the conceptual distinction between the ‘comprehension-expression’ organization and the ‘semantics- syntax’ one will be (partly) justified.

The ‘comprehension-expression’ organization and the ‘semantics- syntax’ one involve two different systems of classification, which are not mutually excluding. If correctly validated, both are plausible systems of verbal organization and interpretation. Comprehension involves both semantics and syntax, and the same applies to expression. Simultaneously, and if semantics and syntax are in fact psychologically dissociable processes, semantics would involve both comprehension and expression, and the same would apply to syntax (e.g., if the evaluation begins with syntax, then syntactic comprehension and syntactic expression will have to be evaluated). Within this line of reasoning, if comprehension and expression neurobiologically overlap it would be expectable that semantics and syntax also overlap.

Alternatively, there is a frequent confusion between comprehension and semantics on the one hand, and between expression and syntax on the other hand, which will not be discussed here. Both systems of organization are interlaced but different. When people are verbally expressing or comprehending something, they are using the resources of semantics and syntax.²³ But when semantics and syntax are established as the initial and broader categories of analysis, then verbal comprehension and expression will function as their sub-categories or components.

There are also some pragmatic differences between both systems of classification: Unlike the dissociation between comprehension and expression, the dissociation between semantics

²² To be more specific: Hagoort and Indefrey [17] conducted a meta-analysis of neuroimaging studies which dealt with sentence comprehension in healthy participants; Catani and Bambini [16] also reviewed neuroimaging studies but mainly pointing at the recent advances in tractography, Catani and Bambini [16], on the other hand, also incorporated some PPA observations.

²³ Vice versa cannot be that naturally said because semantics and syntax cannot be directly observed as behaviors.

and syntax is not easy to observe even using complex linguistic evaluations. Maybe this is so because the semantics- syntax organization was more conceptually conceived and used in academic and linguistic settings where, still today, there is debate about the differences between semantics and syntax. The concepts of autonomy, assessment, hierarchy, interdiscipline, models of evaluation and interpretation, among other topics, are still discussed in relation to semantics and syntax. Additionally, some new neurobiological models on the matter tend to exclude comprehension and expression from analysis even though the psychological dissociation between those two functions is naturally conceived and observed by any person. Parents, teachers, caregivers, nurses, and so on may frequently say: ‘he/she understands everything but he/she can speak almost nothing’ when referring, e.g., to two-year-old children or to patients with nonfluent aphasia. It is not necessary to be a neuroscientist to understand the concepts of verbal comprehension and expression. (Obviously, it is also simpler for neuroscientists to understand, explore and operationalize those concepts than the concepts of semantics and syntax). Accordingly, it is common knowledge that the behavior of verbal comprehension appears earlier in the ontogeny than verbal expression. As well, it can be observed in clinical settings that comprehension is usually recovered before expression after brain injury, and that comprehension is a strong condition for social adaptation and for recovering expression: if comprehension is not considerably (and quickly) recovered, the prognosis for the patient is poor.

Considering some pragmatic differences between both systems of classification in the field of aphasia, it is logically and empirically plausible to verify the following statement:²⁴ ‘without comprehension, it cannot be a coherent expression’, which is true (see below). It is also logically and empirically plausible to verify that ‘without a coherent expression, it cannot be comprehension’, which is false; nonfluent aphasia is an example.²⁵ Unfortunately, similar statements are difficult or impossible to verify in the ‘semantics-syntax’ system, and this difficulty goes beyond the field of aphasia. For example, the affirmation: ‘without semantics, it cannot be a coherent syntax’ is dependent on the position in which both concepts are pondered. For example, for authors who consider that syntax is underpinned on the underlying semantic intention or perception, the statement is true. For those who consider that syntax is a formal reasoning, the first part of the statement (the antecedent) is irrelevant and, so, the statement itself is irrelevant. For those authors who consider that the antecedent and the consequence are relevant, the statement will only be logically and empirically verifiable if the sentential syntax is considered along with its semantic content. Under such circumstances, authors specifically verify what happens with or without semantics. The other way around (‘without a coherent syntax, it cannot be semantics’) is also difficult to analyze.²⁶ For example, and even for authors who, avoiding radical views, specifically verify what happens

²⁴ Of course, comprehension, expression, semantics, and syntax are not dichotomous variables. The examples are specified with didactic purposes to show the complexity of comparisons. Besides, all those concepts are not equivalent.

²⁵ It could be said that, in the particular case of nonfluent aphasia, the function of comprehension acts rather independently of the function of expression.

²⁶ If: 1) semantics is considered synonymous with the whole sentential meaning, and: 2) a coherent syntax with such concept of semantics is considered synonymous with ‘a sentence’, then the sentential semantic unit (or gestalt) cannot be reduced to its elementary units. For radical views, there will be radical outcomes. E.g., for authors who consider that a coherent syntax (as a formal reasoning) is responsible for the meaning of any sentence, the statement is true.

with or without a coherent syntax [17], it is difficult to say if the supposedly syntactic associations are in fact syntactic or semantic associations (see above the ‘semantic consequences’ of some syntactically coherent (and conventional) sentential examples [17]).²⁷ In any case, the semantics-syntax system is logically and empirically more complex and devious to analyze than the comprehensive-expressive system.

In spite of this, and considering the new neurolinguistic models on the matter [16, 17] it seems that, while the dissociation between comprehension and expression is not reflected in anatomical sites, the dissociation between semantics and syntax is, anatomically, clearly observed.

Beyond such widespread (and amazingly consistent) neurobiological findings, the psychological interpretations about the semantics-syntax system remain ambiguous.

Hagoort and Indefrey [17], for example, affirm:

‘Given that speaking and listening have different processing requirements, the same areas may not be recruited to the same degree in these two cases ... This difference between speaking and listening, however, does not detract from the finding that when needed, the same areas subserve unification operations in language production and language comprehension. Even less clear is the degree of separation between networks for syntactic and semantic unification.’ pp 350²⁸

However, Hagoort and Indefrey [17] finally conclude:

‘...there is strong evidence for shared circuitry for core aspects of sentence-level language production and comprehension’ thus confirming once more that the key psychological aspects to understand the neurobiological basis for language are semantics and syntax, although it is not psychologically quite clear what they are.’ pp 359.

Regarding this issue, some unanswered questions will remain: If semantics and syntax cannot be psychologically and unquestionably dissociated (or the dissociation depends on theoretical/ abstract linguistic taxonomies, rather than on objective behaviors); why are semantics and syntax neurobiologically dissociated? Why are the neurobiological findings taken as evidence of the psychological dissociation between semantics and syntax thus discarding their interaction? Neurobiologically speaking: Why comprehension and expression overlap but semantics and syntax do not overlap if all these functions are not mutually excluding? Is it possible that researchers are measuring linear versus nonlinear neurolinguistic processes, or sequentially- perceived versus simultaneously- perceived semantic units? The underlying epistemological viewpoint will determine the way of validation of all these functions, and their interactions, in future studies.

²⁷ See also the definition of ‘a sentence’ given in the initial comments of this article, in particular for non conventional syntactic structures.

²⁸ See above (in a footnote) the meaning of ‘unification.’

SOME QUESTIONS ABOUT APHASIA ANALYZED WITHIN THE NEW EPISTEMOLOGICAL FRAMEWORK

Trying to ignore all the disquisitions expressed above regarding the characteristics of semantics and syntax, and trying to assume that: a) semantics and syntax do not differ in quality (explicitly, that they are comparable linguistic processes), b) the parts and the whole are equally important for both processes, and c) all the factors which eventually differentiate both processes can be manipulated by controlling experimental commands and conditions, two consequences for the aphasia topic can be proposed:

- 1) Patients with nonfluent/agrammatic aphasia (who supposedly have morphosyntactic impairments) cannot form words or bigger verbal constructions correctly. Maybe these patients can sometimes utter isolated words or even isolated sentences correctly but the rule is that they cannot properly form words, sentences and so on. That is so because they cannot link the components of those units.²⁹ Beyond the fact that agrammatism in itself implies that some words are missing, if it is also assumed that these patients really have morphosyntactic impairments, then they should have trouble with naming. However, in the PPA guidelines, for example, impaired naming is not described as a symptom for this type of aphasia [3]; patients with nonfluent/agrammatic aphasia only have ‘inconsistent speech sound errors’ for otherwise semantically correct units. That is so even though the observational boundary between sound errors and phonological errors is diffuse: Both types of error may produce phonetic /phonemic paraphasias of any size (including small scale problems such as difficulties with a single sound or letter per word).³⁰ On the other hand, it would be incorrect to reason that patients with nonfluent/agrammatic aphasia show a correct speech just for semantic units at the single-word level because the lack of fluency can go from subtle impairments to mutism, thus covering a wide range of expressive semantic impairments. This range would go from simple word-distorting phonemes, morphemes (of any type) passing through single-words, to finally reach sentences, paragraphs, and so on. Or from the opposite perspective, if it is assumed that these patients do not have semantic impairments, then any semantic unit should be preserved, which is false. Sentences and words are incomplete, disorganized, and distorted because the whole expression is imprecise and nonfluent. Additionally, if the syntactic analysis is defined as a superior mechanism which organizes the inferior level of semantics [16, 17], when the superior mechanism is affected, the inferior one will become disorganized. I.e., if syntax is affected, semantics will be affected.

²⁹ Just as a comment: The impaired comprehension of syntactically complex sentences is considered by some authors a symptom of nonfluent aphasia (see, e.g., [3]). In our experience, it may be a common disturbance of brain injured patients in general; it is not pathognomonic of patients with nonfluent aphasia and, so, it is not a valid construct for this aphasia. Reciprocally, patients with any type of aphasia usually have many cognitive domains impaired [9, 29].

³⁰ Some deficits described in the PPA guidelines [3] are difficult to verify; for example: ‘effortful, halting speech with inconsistent speech sound errors...’ which belongs to the agrammatic variant, versus ‘speech (phonologic) errors in spontaneous speech ...’ which belongs to the logopenic variant. These deficits are not usually shown by means of empirical definitions in PPA studies, thus leaving to the discretion of each observer the final interpretation.

Independently of the above said and trying to understand this position, it could be thought the following: Cognitive functions which are less crystallized, less frequently used, more complex, or later acquired, tend to be the most vulnerable to brain injury. If that is so, and considering that syntactic ability is a late acquisition; is it probable that only the most formal details of verbal language are affected in patients with nonfluent/agrammatic thus producing a less sophisticated speech? If this temporal gradient really exists for syntactic functions; is there a possibility that nonfluent aphasia could be a less severe aphasia -rather than a different type of aphasia- in relation to the fluent one [34]? ³¹ Or from the opposite perspective, if it is assumed that semantics (which include nonverbal and multimodal signifier and signified sub-systems) is a more extended, crystallized, and resistant linguistic function in the brain; is it possible that all such neurolinguistic system inhibit the (pure semantic) naming errors in nonfluent aphasia? If this neurofunctional gradient really exists for semantic functions; is there a possibility that nonfluent aphasia could be a less severe aphasia -rather than a different type of aphasia- in relation to the fluent one?

Regarding just syntactic expression, it is difficult to understand the affirmation of Catani and Bambini [31] that there is one single restricted area in the brain which triggers verbal fluency. ³² According to that finding, the frontal aslant tract would activate morphosyntactic concatenations not only independently of the rest of the cognitive functions, but also independently of grammatical or repetition deficits. By assuming that such excitatory (pure frontal) site exists [16, 31]; is it possible that its inhibitory counterpart is verbal comprehension [34]? If the ability of action monitoring (see Bonini et al., [36] quoted by Catani and Bambini, [16]) is conceptually added to the function of pure verbal fluency of the frontal aslant tract, then it could be deduced an inhibitory counterpart for pure verbal fluency.³³ Obviously, that would be so on the assumption that action monitoring [36] also encompasses verbal language monitoring. Without going so far, and by only considering the verbal language system, if it is assumed that comprehension involves an extended brain network in the left hemisphere, comprehension can be such inhibitory counterpart.

- 2) Patients with fluent aphasia (who supposedly have impairments in the most basic semantic units), cannot retrieve words and cannot understand the meaning of those words correctly. Maybe these patients can speak a lot, or link many verbal units; maybe the quantity of language production is adequate or even exacerbated, but the rule is that the quality of utterances is incorrect. As a result, these patients can neither utter words nor form bigger verbal constructions correctly: Paraphasias of any type, confusion between previous and subsequent words within a sentence, confusion between previous and subsequent phonemes/ sounds within a word; ‘word salad’, jargon, intrusions, perseverations, as well as circumlocution, anomia, and word-finding difficulties can be observed in patients with fluent aphasia. As they cannot retrieve and understand single words, more so they cannot retrieve and understand relationships among multiple words. Curiously, some authors believe that these patients have preserved syntax [3].

³¹ Accordingly, is there a possibility that nonfluent aphasia could be the first to appear and/or the more frequent aphasia?

³² Peterson and Hagoort [35] affirm: ‘For language, as for other cognitive functions, the function-to-structure mapping as one-area-one-function (as currently conceptualized) is likely to be incorrect. Brain regions typically participate dynamically as nodes in more than one functional network...’

³³ It is worth remembering that the frontal aslant tract does not belong to the level of syntactic analysis in the model of Catani & Bambini [16],

However, if the most basic semantic units are ambiguous, disordered or absent; how can they be uttered without affecting syntax? Patients with fluent/ semantic aphasia cannot have a 'fluent language' because they cannot name and/or comprehend, among other impairments. They show substitutions, omissions, inversions, distortions and so on for phonemes, graphemes, words (of any type), sentences and bigger verbal constructions. Yet, and considering PPA [3] it is stated that, in the semantic variant, syntax is spared. Wilson, et al., [37] affirm that 'syntactic deficits can be defined as limitations in syntactic processing, which may be manifest in production, in comprehension, or most typically, in both production and comprehension.' Subsequently, those authors affirm (with 'robust body of evidence') that in most patients with semantic variant PPA, syntactic processing is strikingly spared. However, and considering more experimental paradigms [5, 17], even if patients are recruited [5], syntax can only be evaluated if semantics is spared.

Returning to the relationship between fluency and aphasia [31] previously analyzed in nonfluent aphasia, it is reasonable to conceive that, in fluent aphasia, the function of fluency is triggered in view of the lack of comprehension. Nevertheless, as the articulation or linking mechanisms (in the same way as the word retrieval mechanisms) cannot be monitored and amended, an appropriate sequence in the units of the language cannot be expected either. Interestingly, if there is a brain site which triggers verbal fluency independently of its quality (i.e., 'how much' a person speaks independently of 'how well' [38, 39]) that could explain why patients with fluent aphasia speak neither accurately in the semantics nor in the syntax.³⁴

Unlike the expressed in the preceding paragraph, and trying to understand the affirmation of Wilson, et al., [37] regarding syntactic preservation in the PPA semantic variant, it could be thought the following: Although the ability to retrieve words and the ability to link words are mechanisms with an important automated component, maybe it is effortless to bring awareness the syntactic linear rules than the semantic nonlinear ones, e.g., it could be effortless to remember that an article comes before a noun than to unravel the intricate (and more automated) semantic relationships among word families. Even assuming that the syntactic rule might be perfectly retrieved by these means, the interaction with the retrieval of the rest of words cannot leave aside. Under such circumstances, patients might be able to use syntactic structures but all types of erroneous words will be placed inside those structures. For example, articles will be searched from the semantic family of article words which, for having fewer options (and less complexity) than the family of nouns, will yield fewer errors than nouns but, finally, the organization of sentences will be affected by the use of multiplicity of quasi articles followed by quasi nouns and so on.

In summary, and even using the new way of thinking, it is expectable that nonfluent aphasia shows semantic problems and fluent aphasia shows syntactic problems. It is also possible that there is just a degree difference between both aphasias.

³⁴ Analyzing the PPA guidelines [3] it seems that patients with nonfluent aphasia only have problems with the quantity of expression, and patients with fluent aphasia only have problems with the quality of expression. Quantity and quality were used in the item: Evaluation of Spontaneous Speech in the Brief Aphasia Evaluation [38, 39] but the deficit was analyzed, in this case, as a combination of both attributes.

APHASIA AND SOME OF ITS METHODOLOGICAL CONTROVERSIES UNDER THE PRESENT WORK PERSPECTIVE

Taking into consideration the comprehension-expression system and studying samples of patients and healthy participants, Vigliecca and Baez [29] carried out an integrative (empirical) study addressed to obtain better definitions for verbal functions and sub-functions including: a) their organization under a hierarchical model, b) a lesion-based approach, and c) the analysis of a homogenously verbal and short aphasia test. Using confirmatory factor analysis and the Brief Aphasia Evaluation (BAE), a valid explanatory model for the neuropsychological characterization of aphasia” was proposed.

The model encompassed [29]:

- a) An all inclusive verbal organizer from which two successive organizers emerged.

The two successive organizers were:

- b) A more general classification which essentially included verbal comprehension and expression, in addition to a “complementary” verbal factor which included praxia, attention, and memory.
- c) A more specific classification which included the individual (and correlated) constructs of auditory comprehension, repetition, naming, speech, reading, writing, and the “complementary” functions.³⁵

By following this approach (where the aphasia patterns are exhaustively analyzed) all the patients fall inside the classification system; consequently, the gradual improvement of the aphasia theory is guaranteed. On the contrary, when only certain types (and number) of aphasias are considered as valid, without empirically demonstrating why other combinations of symptoms are not, the double dissociation which otherwise would be explicit becomes impossible to verify. The present probabilistic approach allows verifying this type of dissociation because any combination of symptoms is detected (and shown) and the theoretical interpretation is not left to chance. Additionally, as any pattern of the latent language impairments can be recognized, neurorehabilitation professionals are able to work with the particular characteristics of the patient, without being forced to follow a predetermined diagnosis typology. The model proposed in that work may represent a valid tool in the attempt to find new classifications or constructs for aphasia disorders (and their biological causes) beyond some widespread definitions and typologies [29].

New models concerning aphasia definitions, classifications, and their relationship with brain networks are necessary in particular because, so far, serious methodological inaccuracies can be verified in the available models.

Despite significant improvements observed in the psychological methods during the last years, the psychological outcomes are still puzzling. In the Publication Manual of the American Psychological Association [40], the methodological need of describing in detail the

³⁵ It is worth noting that, except for the “complementary” functions, all the underlying verbal constructs follow the behavioral order of appearance in the ontogeny.

variable conceptual and operational definitions is stated. However this is not fully respected, particularly in clinical settings.

If the conceptual and the operational definitions are confused, the theory gets into an endless loop in view of the lack of distinction between conceptual agreement and real proofs [4, 26]. As concepts are still used during the phase of empirical validation, the hyper production of pseudoscientific articles becomes facilitated. Additionally, the use of typical cases seriously restricts progress [41].³⁶

By using the method of selecting patients according to quantitative suggestions such as: ‘at least one of these criteria’, ‘criteria X to Y must be absent’, ‘at least 2 of 3 criteria’, etc., patients are actually grouped according to the number of present indicators (from zero to all the indicators). Although this method may produce hundreds or thousands of groups, experts only consider less than a handful of groups, which are in fact just ‘the typical cases’. As the empirical/ operational definition is not exhaustive, the classification of ‘the real cases’ is impossible to be accomplished. Finally, the typical-case classification is exclusively made by expert-based evaluation.

‘Under a correct empirical definition, all the cases should be feasible of classification but if real persons are confounded with ideals, many cases will be left out. That is why conceptual definitions should not be used for empirical demonstrations’ [26].

When certain psychological qualities are intentionally selected to construct a ‘typical’ pattern so that such pattern agrees with what is expected by a theory, the pattern is constructed *a priori* and the research is biased. I.e., when only the diagnosis categories which confirm the syndromic hypothesis are included, the work is not scientific because there is no way of verifying the actual syndromic pattern in either the excluded cases or the compulsorily included ones.

In the case of aphasia, if only certain combinations of indicators are taken as the key ones for classifying patients in just, let’s say, three aphasia categories (of the thousands of possibilities), then, those three categories will be at once the conceptual and the operational definitions. That is so because the patients’ real responses are forced to go to those three conceptual categories. Since the categories of the dependent variable are constrained to be, as much as possible, the three initially conceived, methodological circularity is produced.³⁷

This methodological difficulty can be seen in a paragraph taken from Mesulam, et al., [2]. The paragraph shows that 20% of the patients were (empirically) chosen to be included in the (conceptually) predetermined categories, namely, agrammatic (PPA-G), semantic (PPA-S), and logopenic (PPA-L) variants, in order to improve subtyping during demonstration. I.e., these authors went back to the concepts during the result section of the study, more specifically, during ‘the empirical validation of the classification guidelines’, even if the quantitative criteria (the tests, the cut-off points and the empirical definition) had already been selected. Mesulam, et al., [2] wrote the following theoretical interpretations in the Results (instead of writing them in the Discussion):

³⁶ This trend to use typologies can be illustrated with an analogous example in which three socioeconomic levels have to be empirically defined by using 15 supposed indicators [41]: If inexperienced evaluators are involved, they will tend to define just three ‘cases’: the typical multimillionaire, the typical representative of the middle class, and the undeniable poor. Thus, almost 0% of all the possible cases would be classified.

³⁷ Even the empirical definitions of the Western Aphasia Battery have not been exhaustively constructed since the cut-off points do not consider all the possible combinations among symptoms [42].

‘The classification guidelines of Table 1 lead to some ambiguity in differentiating PPA-G from PPA-L. For example, a patient with agrammatism, impaired repetition, impaired single-word retrieval and phonemic paraphasias would fulfil the criteria for both variants as long as motor speech, single word comprehension and object knowledge are spared. Thus, Patients 5, 8, 15, 17 and 20 fulfilled criteria for PPA-G as well as PPA-L. We chose to include the former two in the PPA-G group because of the prominent agrammatism and the remaining three in the PPA-L group because we interpreted the exclusionary criterion number 4 for PPA-L in Table 1 (‘absence of “frank” agrammatism’) specifically to designate ‘prominent’ abnormalities of grammaticality, such as those that should lead to overt morphosyntax errors in speech’ [2] pp 1544.

Apparently, by applying a combination between the empirical definition and the clinical/conceptual one, subtyping was improved. In this work, the authors wanted to test whether the recently published classification guidelines for subtyping PPA into agrammatic, semantic and logopenic subtypes [3] could be applied to patients with mild impairment. Regarding this outcome and the overlapping criteria for agrammatic and logopenic subtypes of primary progressive aphasia, Mesulam et al., [2] affirm: ‘Quantitative criteria were least effective in the distinction of the agrammatic from the logopenic variant and left considerable latitude to clinical judgment.’

This is an example in which the division between the theory, the methods, and the results is not clear. Moreover, if patients’ recruitment is based on this combination between the empirical definition and the conceptual one (instead of being based on an independent empirical definition) most of the cases of the dependent variable will be the theoretically expected ones.

To stop contaminating the results of the instruments (the real patient’s data) from previous conceptual definitions [4], the deductive inference from the concepts to the symptoms (the empirical indexes) should come first and, at the end of the research, separately, the inductive inference (the interpretations) from the symptoms to the conceptual syndromes. Otherwise, the initial syndromic typology may become unalterable and the exhaustivity of the potential aphasia patterns (the real syndromes) may be lost.

The most convenient way to improve the aphasia theory is to incorporate all the mixed cases in the classification, which is equivalent to say that ‘all’ the patients are included. Since most of the patients have mixed (not typical) clinical manifestations [1, 41, 43], all the response possibilities have to be collected. If a psychological technique has the appropriate psychometric properties, a simple sum of scores is sufficient to cover all the response possibilities and get a correct empirical definition. Since such definition has to be made with the instruments of each laboratory, there cannot be a universal empirical/ operational definition. Additionally, the use of different empirical approaches serves to ensure that the scientific progress does not stay fixed under a dominant position. ‘Unfortunately, most of the clinical definitions of typical syndromes have passed down from generation to generation based on tradition and agreement rather than on demonstration.’ [29]. It is expected that this trend changes with the improvement of psychological methods.

Although, methodologically speaking, there is not much difference between the variants proposed in the PPA guidelines [3] and those proposed in the classical aphasia syndromes [44, 45], the PPA classification uses more indicators (from 8 to 13 approximately, instead of 6) thus increasing the number of possibilities of combining symptoms and forming

syndromes (from 256 to 8,192 possible syndromic groups, instead of 64 [46]). Since impairments in semantic and syntactic functions are included in the PPA guidelines, experts had to incorporate more indicators to assess those symptoms. Additionally, and even if pure language impairments are extremely frequent in the scope, experts are compelled to combine symptoms to form more complex syndromes to respect the theoretical guidelines, e.g., a patient with semantic aphasia has to show troubles with naming ‘and’ comprehension. In the work of Mesulam et al., [2], 12% of the patients were not classifiable by the PPA guidelines. The authors stated: ‘All three stood out because of pronounced abnormalities in object naming. They came close to fulfilling the criteria for PPA-S except that word comprehension was preserved.’ Obviously, this would not happen under a suitable operational definition. The 20% quoted above, and the 12% quoted here would be included.

In the psychological typology proposed by the so-called classical approach, various language functions are simultaneously evaluated in order to detect typical aphasia syndromes or pure language impairments. Four basic language functions (repetition, comprehension, expression, and naming) and two complementary ones (reading and writing) are usually studied as the elementary aphasia constructs or symptoms. However, at least eight aphasia syndromes (Broca, Wernicke, conduction, anomic, transcortical sensorial, transcortical motor, transcortical mixed, subcortical) and at least three pure language impairments (alexia, agraphia, verbal deafness) are deduced from the elementary constructs. While the elementary constructs are at most six, the diagnoses are at least eleven. Yet, the diagnoses keep increasing because they have not been exhaustively defined and many aphasia patterns fall outside the classification system [47].

A similar increase of syndromes can also be observed for PPA in just four years: Three [3], four [2], or even six [31] variants (the semantic, logopenic, nonfluent, and/or agrammatic as well as the mixed and severe ones) have been described. Considering the 12% excluded above [2] maybe anomic aphasia could be computed as the seventh variant.

Recently, Mesulam and Weintraub [48] wrote a commentary (with the name: ‘Is it time to revisit the classification guidelines for primary progressive aphasia?’) in which they said:

‘Hair-splitting details of syndromic classification can hardly be expected to attract much attention. As in all areas of science, however, sound nosology and uniform nomenclature are important for progress in neurology. This is particularly true for the neurodegenerative syndromes, including primary progressive aphasia (PPA), where heterogeneity of phenotype and cellular pathology has defied attempts to coherent clinicopathologic correlations.’ pp 1108

The commentary was about an article of Wicklund et al., [49] where it was studied how well the consensus criteria could classify subjects with primary progressive aphasia (PPA) by following a quantitative approach. Thirty one percent of participants with a neurodegenerative speech and language disorder could not be classified, and twenty percent showed apraxia of speech without aphasia. The authors conclude: Application of consensus PPA criteria yields the three syndromic variants but leaves a large proportion unclassified. Therefore, the current consensus criteria need to be modified in order to improve sensitivity.

At the same time Mesulam et al., [50] observed that:

‘Individual features of the aphasia, such as agrammatism and comprehension impairment, were as informative of underlying pathology as more laborious subtype diagnoses. At the single patient level, no clinical pattern was pathognomonic of a specific neuropathology type, highlighting the critical role of biomarkers for diagnosing the underlying disease. During clinical subtyping, some patients were unclassifiable by the 2011 guidelines whereas others simultaneously fit two subtypes. Revisions of criteria for logopenic primary progressive aphasia are proposed to address these challenges’ pp 1176.

As shown in these quotations, psychological assessments are not relevant by themselves. Apparently, they can only be estimated as relevant if they help to find biological markers.

The syndromes of the PPA guidelines [3] were proposed to divide the clinical manifestations of PPA based on specific speech and language features characteristic of each subtype. However, if all of those theoretical syndromes have never been psychologically validated, they cannot be used as the gold standard for validating other measures addressed to assess, precisely, those syndromes (see, for example, Agosta et al., [33], described above).

In addition, aphasia patterns have to be discovered independently of their biological basis in order to avoid circularity. Nevertheless, this is impossible to do if brain imaging, neurobiological/ neurofunctional patterns, and/ or other biological indices are put together with the psychological patterns in the consensus diagnosis guidelines.

THE ‘OLD-FASHIONED’ VIEW OF PSYCHOMETRY

A psychological disorder and its biological causes cannot be established by convention.

The impetus to reach agreement with psychological events has led to the shocking situation in which a consensus-criterion article published in 1984, for example [51], has been quoted almost 22,000 times by April of 2015 as synonymous with the procedure for demonstrating diagnosis. Considering the guidelines of 2011 for primary progressive aphasia, that number was almost 800 in just four years [3].³⁸ As such psychological criteria were established by authority, its ‘validity’ does not require demonstration. Subsequently, clinicians and researchers are authorized to diagnose and treat patients without any other requirement than quoting those criteria. Within a certain clinical topic, there will basically be a single guiding criterion (excluding the almost identical ones), until the experts meet again. At the same time, journal reviewers usually demand that such criterion is quoted in the articles. In such a way, all the material and human resources are put at the service of the guiding consensus proposal, being the resources put at the service of getting *post-hoc* empirical validation the most noticeable.

Validity in psychology is usually confused with agreement, and agreement is usually confused with empirical consistency. By this mean, the intersubjective consensus of experts becomes a ‘theory’ and the subsequent studies will tend to confirm it, with minor details. As previously explained, all this occurs because the pattern of the patient’s psychological data is conceptually (not empirically) built. Finally, the supposed consistency is magnified by dissemination.

³⁸ For researchers who have been formed with an experimental approach that situation is at least irregular. Methodological quality and reasoning have lost value in favor of the quantity of information as well as the reproduction (rather than the renovation) of contents and approaches.

A theory should be defined as 'scientific' by its method, not by its content, not by its data-collection techniques and, much less, by the name of its authors or its widespread application. Present consensus definitions are essentially based on literature reviews as well as the number of publication of the authors involved. Unlike consensus, a proposal based on logical and mathematical principles is independent of prestige.

Since prestigious subjectivity is a more powerful subjectivity, the initial (well-intentioned) attempt to avoid psychological subjectivity turned out to be counterproductive: An incorrect epistemological structure is worldwide encouraged to be the same from the beginning to the end of the research so that the choices lean toward staying in the same conceptual system. Considering that without change there is no improvement, scientific knowledge is hindered.

In the 'consensus' articles it is usually written: a) the psychological diagnosis was made by some expert X according to the consensus definition Y,³⁹ b) the technique Z (which generally represents the originality of the research) was applied to the diagnosed groups, and c) the results are...

Since no demonstration is needed for the first step, neither expertise nor the consensus definition is empirically verified [4]. Regarding psychological diagnosis, the question that arises is the following: If it is true that all the corresponding psychological instruments have been applied for diagnosis; why their results are not (completely) shown?

Fortunately, the manifestations of psychological disorders are increasingly demanded to be more objectively proven. Such methodological demand is probably bringing about a little more frequent emergence of proposals aimed to renovate the consensus criteria. These proposals are refreshing since it is expected that literature reviews and, particularly, diagnosis guidelines change all the time according to the renewal of empirical findings. However, this change is very slow in view of the redundant framework on which the prevailing viewpoint rests. At present, and considering the new methodological demands, maybe the question expressed above has to be reformulated as follows: If the psychological results have to be shown; why the predetermined patterns of responses appear practically indistinguishable at the beginning and at the end of the research?

When reasoning is wrong it can be anticipated that the results will be wrong, but when most of the studies tend to confirm the consensus theory, something serious occurs, something that exceeds (or makes useless) scientific methodology and logics.⁴⁰

Nowadays, there are a lot of coincident reviews with 'undisputable' inferences where brain images are highlighted as a sort of (psychological) validation procedure in itself. It is quite the opposite view of the classical aphasia approach when the brain images were absent. Between both extremes of such an imaginary pendulum, the validity of psychological tasks and experimental designs remain obscure. In both extremes, psychological interpretations and preconceptions are dominant. Besides, scientific reviews seem to be captive of previous renowned findings. Although pioneering works and their authors are remarkable, that is not a

³⁹ If the theory is not valid, and the supposed expert is functional to the theory, then the expert can turn out to be inexpert for other theories. He/ she may not be able to see the variable categories and clusters of the other theories and, so, there may be (unintentional) bias due to such singular expertise.

⁴⁰ It can be useful to remember that expert-consensus overvaluation was one of the causes of the scientific impasse in the middle age. At the present time, and considering the problems generated by the globalization, Science must be more than ever independent of the Establishment. However, proposals and articles of renowned scientists and journals have now become synonymous with better and forced-to-be-quoted ones. They represent 'the' dissertations of reference.

reason for repeating them indefinitely. Moreover, if attention is not paid, this may be a way of getting stuck.

Even if dissent and the questions which cannot be answered by the present theory are the keys for generating scientific progress, they are usually avoided. On the contrary, there is a sort of constant search for consistency and widespread validation. Article reviews must look for similarities and differences but, for some reason, reviewers tend to seek similarities as much as possible.

Twenty five years ago Summers and Lederman [52] wrote something that is applicable to the present time and topic: 'Literature reviews... emphasize positive results, down-playing the null findings and extensive methodological inadequacies in the published...studies.'

Additionally, the link between psychosocial and biological sciences has created new challenges. For example, the direct transference from medicine to psychology of the methodological structure to construct nosologies has lead to considering psychological symptoms as if they were physical. But psychological symptoms need to be first translated to 'physical signs' (to put the expression in medical words) in order to be objectively assessed and then, secondarily, interpreted. Such translation is the operational definition. The association observed between a measure obtained with a biological technique and a measure obtained with a psychological technique is not equivalent to the translation of psychological symptoms or syndromes to observational 'signs'.

The ability to link psychological aspects with more organic (and supposedly more objective) substrates has produced a sort of euphoria that tend to obscure the fact that psychological aspects remain today as difficult to assess as throughout history. The validation of one psychological symptom is complicated, but the validation of several syndromes is much more complicated. Yet, the proposal of psychological syndromes is rife these days. The biologicistic trend is predisposed to believe that psychological events are quite 'freely negotiable', until a biological marker appears.

If the interaction between medical and psychological nosologies do not involve logical reasoning for deciphering the genesis and organizational structure of their concepts, including the basic distinction between the independent and dependent variables [4], the interdisciplinary efforts might enter into a speculative vortex similar to the observed in very ancient times or in the always present psychological pseudoscience.

Operationalization is part of the standard procedure to develop psychological studies and instruments. It is a useful step to deduce objective evaluations from concept/ consensus definitions; thus, it is a necessary step within each research which involves psychological assessment. Unlike the concept/ consensus definitions, which rely on authority, the validity of the psychological operational definitions does require empirical demonstration. However, with the advent of the clinical definitions by consensus (paradoxically presented as 'operationalizations') the specific study of the psychological assessment has lost status and high impact journals are not interested in psychometrics. On the contrary if a revolutionary neurobiological technique interacts with a psychological outcome, the research will be interesting, no matter the details of the psychological assessments, if they are shown at all.⁴¹

⁴¹ The confusion between the validation of the psychological assessments, on the one hand, and the validation of the study itself, on the other hand, also produces confusion among all the steps and procedures involved in the research. For example, if it is stated in the Methods, that the independent and dependent variables to be shown in the Results are highly correlated, the only step left for the rest of the research will be to describe the results of the already known correlation. It is very common these days that psychological assessments and their

Nevertheless, the neurobiological techniques also require validation and, curiously, such validation comes from psychology. Since the concurrent validity involves a two-way implication, the psychological validation is a necessary condition for demonstrating the neurobiological one.

A valid conceptual classification for aphasia symptoms and syndromes (or verbal functions and their organization), according to biological evidence, is necessary not only for discovering the dissociations and interactions among neuropsychological functions, but also for studying the consistency among different approaches, samples and instruments. This theoretical model should go beyond the novelty of the circumstantial instrument used for data collection, require deep methodological considerations and, if so, it will result in better research, therapeutic or preventive proposals. Neuropsychology has two parts. When article reviews are done, the psychological validity of tests and experimental designs has to be analyzed along with the neurobiological outcomes. If the consistency among neurobiological outcomes is based on doubtful psychological outcomes, the theoretical inferences will be doubtful.⁴² To be more specific, if the validity of the psychological outcomes is doubtful, any language neurobiological model will be doubtful.

A correct approach in the field of aphasia demands that the psychological symptoms and clusters of symptoms are defined in relative terms so that the interaction with lesions and clusters of lesions can be established by demonstration. Although there are some new attempts of modeling the relationship between brain and language, they mainly accentuate bibliographic and neurobiological consistency. I.e., psychological manifestations and interpretations can apparently remain open (or secondary) in view of the neurobiological evidences. Maybe for this reason the neurobiological evidences are so consistent while the psychological ones are not.

Psychometry helps to discover the validity of the instruments as well as the dissociations and interactions among psychological functions. In clinical settings, for example, if the consensus guidelines state that other cognitive disturbances have to be dissociated from aphasia, such dissociations have to be shown in the research. Beyond the guidelines, if a certain test is proposed to assess, e.g., grammatical- processing, and the test involves reading, the dissociation which demonstrates that grammatical- processing is independent of reading has to be shown.

The contribution of psychometrics to the neurosciences in general and to the aphasia theory improvement in particular has to be reconsidered. The feedback that exists between theory and instrument is best understood under this perspective. Although the instruments are based on the theory to prove their validity, they simultaneously serve to improve the validity of the theory. To avoid that this virtuous circle becomes a vicious one, all the steps of the scientific method has to be respected and dissociated from each other. As seen above, this objective is far from being achieved.

properties are *ad hoc* shown, wherever they become more convenient. Therefore, they can be at once the cause and the consequence.

⁴² Currently, most of the authors seem to share the approach which goes from psychology to neurobiology. Beyond the fact that, for aphasia (and by definition), the opposite direction should prevail, it would be interesting to see more frequently the exploration of the verbal-language functions as dependent variables: from neurobiology to psychology.

Considering aphasia diagnosis, only when the patterns have been consistently validated through different laboratories and approaches, they can be proposed as a theory. Otherwise it may be more useful to continue just with the symptoms.

Chapter 87

ACQUIRED CHILDHOOD APHASIA: A MOSTLY UNKNOWN PHENOMENON

Melanie Kubandt*

University of Osnabrueck, Department of Education,
Section Early Childhood Education, Osnabrueck, Germany

ABSTRACT

Acquired Childhood Aphasia (ACA) is a medical phenomenon which is still mostly unknown and often disregarded. One reason for this disregard is the rarity of aphasia in children often being emphasized, and the prognosis being assumed to be more favorable for children and adolescents than for adults. Another common reason for the disregard is the lack of understanding the clinical picture of aphasia in children. The provided chapter offers a broad overview of possible definitions, symptoms, prognosis and outcomes of Acquired Childhood Aphasia and the impact on quality of life for the affected children and adolescents and their families. It goes on to show that the prognosis is not as favorable as often proclaimed, and impacts the affected children and their families in numerous ways. Finally, this chapter points out possibilities of therapeutic intervention and provides examples of measures of support for the families.

INTRODUCTION

There are numerous reports and research papers on aphasia, or at least on the variety affecting adults. Reports and papers on Acquired Childhood Aphasia (ACA), however, are still being marginalized. Globally speaking, there's the occasional research, notably stemming from Anglophone countries; compared to research papers on adult aphasia, however, are few and far between. This marginalization of ACA encompasses not only the fields of aphasiological research and education, but also the subsections of diagnostics and therapy. However, the last twenty years have shown discernible efforts to intensify research in this

* Corresponding Author Email: melanie.kubandt@uni-osnabrueck.de.

particular area of aphasiology. Various authors have repeatedly drawn attention to the lack of knowledge and research concerning the etiology and concepts of ACA diagnosis and therapy in recent decades. Presently, there's a discernible and increasing focus on ACAs acting as a spotlight on the phenomenon.

APHASIAS IN CHILDREN AND ADOLESCENTS - DEFINITIONS

A pervasive, yet not undisputed criterion for defining aphasia is the completion of language acquisition. However, aphasias are most definitely not limited to adults possessing a complete vocabulary. Damage to the brain, predominantly by way of traumatic brain injury (TBI), can lead to sudden-onset acquired aphasia in children and adolescents (cf. Leischner 1987, Rother 2005, Spencer 2006): "Like adults, children can exhibit language disorders from injury to the central nervous system after a period of normal development. Childhood-acquired language disorder, or childhood-acquired aphasia, refers to language impairment evident after a period of normal language acquisition that is precipitated by, or associated with, an identified form of brain insult." (Dennis 2010, p. 418). Dennis and Barnes (1990) state that head injury is the most common form of acquired brain damage in children and adolescents. Spencer (2006) regards TBI as the leading cause of acquired aphasias in childhood and adolescence, with a prevalence of 80% (cf. Hécaen 1983, Leischner 1987, Paquier/Van Dongen 1993). According to Siegmüller and Heide (2006), children suffer traumatic brain injuries primarily through vehicular accidents, through falling down whilst playing or doing sports or as a consequence of physical violence: "The neurobiology of childhood traumatic brain injury (TBI) includes immediate impact injury (contusions, diffuse axonal damage), secondary intracranial events (hematomas, brain swelling, infections, subarachnoid hemorrhages, hydrocephalus), and extracranial factors (hypoxia, hypotension). TBI results in focal brain damage (vascular injury involving contusions and hemorrhage, especially in the frontal and temporal lobes) and diffuse brain damage (to axons in the white matter), as well as in secondary damage such as raised intracranial pressure, hypoxia, and ischemia" (Dennis 2010, p. 418).

While strokes constitute the most common cause of aphasias in adult patients (in 80% of cases), resulting in unilateral focal lesions, children tend to present with diffuse, most commonly bilateral injuries affecting several cerebral areas to a variable extent. Granted, strokes can also occur in children, but this is among the rarely observed causes of ACA (cf. Spencer 2006).

ACAs show a marked difference in appearance, progression and pathogenetic conditions when compared to aphasias in adults (cf. Poeck/Hacke 2006, p. 102). Among the other possible causes of ACAs are brain tumors, degenerative diseases of the central nervous system, encephalitis and epilepsy (cf. Becker et al. 1986; Fabbro 2004).

Dennis and Barnes (1990) point out: "Recent studies of language in head-injured children and adolescents have concerned three issues: The rate of language recovery; the relationship to language deficits of factors like age, etiology, lesion size, and lesion site; and the form and range of the clinical language disturbances." (ibid. p. 429). If the cerebral language disorder's causes are pre- or perinatal, the affected children won't be able to complete a regular language development. These cases are not referred to as ACA. Some authors roughly

differentiate childhood language disorders as either ‘disorders of speech development’ or ‘ACAs’ (cf. Leischner 1987, p. 268; Rother 2005, p. 90). According to Leischner (1987), these can be further delineated: A disorder of speech development commences at a time when linguistic development has either not yet begun or has not yet been completed. ACA, in contrast, can be defined as the loss of an already acquired faculty of speech, analogous to adult aphasia (cf. Leischner 1987, p. 268). Therefore, only postnatal injuries can by definition be regarded as the cause of ACA (cf. Van Hout 1992; Rother 2005). To what extent aphasias can occur prior to the conclusion of linguistic development, however, is left ambiguous in Leischner’s delineation. In contrast, there are authors who choose to apply the term of ACA to impaired children who have not yet completed their language development (cf. Friederici 1984). This approach has asserted itself in recent years. In this regard, however, Rother (2005) as well as Leischner (1987) emphasize the necessity of aphasia being defined as the degeneration or loss of pre-existent faculties of speech (cf. Rother 2005, p. 91). Van Hout (1992) includes this facet in her by now generally accepted definition of ACA: “(1) An acquired lesion must have occurred after a lesion-free period, a free interval, and thus differs from the lack of language of congenital dysphasias in which the insult is pre- or perinatal; (2) Some normal language must already have been present, the accepted age-dependent boundary usually being 2 years of age, the time of the advent of the first sentences.” (ibid. p. 140). In practice, children are therefore regularly being diagnosed as aphasic even before the completion of language development. The linchpin of this definition is the proficiency in language production. Fabbro (2004) concurs with Van Hout’s definition and adds: „Acquired childhood aphasia refers to language deficits following brain lesions after the age of acquisition of the first sentences, generally after the age of 2.” (ibid. p. 1). This illustrates among other things a fundamental distinction in regards to disorders of speech development, seeing as childhood aphasias are the result of a distinct incident.

ACQUIRED CHILDHOOD APHASIA – NOT THAT COMMON?

Oftentimes, ACA is and has been labelled as a rare disorder. There exist no precise figures with regard to its prevalence and incidence. Guttmann (1942) however casts doubts on the relative rarity of the clinical picture, based on studies conducted more than 70 years ago: “[I]t is surprising that the rarity of aphasia in children is so often emphasized, and I think this can be accounted for only by lack of understanding of the clinical picture of aphasia in children” (ibid. p. 208). Compared to adult-centric aphasiology, Guttmann defines the problem of diagnosis thusly: „Aphasia in the adult is mostly diagnosed or sought for when the patient complains of difficulty in his speech – which children do not do – or if he uses wrong names for objects; in other words, apart from cases of complete motor aphasia, the early diagnosis of aphasia is commonly based on subjective or objective word-amnesia. The clinical appearance in children is different, and the signs of aphasia in a sick, apathetic, shy and often morose child are easily overlooked unless specially sought.” (ibid.).

Satz and Lewis (1993) share these doubts and point towards studies indicating a higher number of children exhibiting aphasic symptoms than commonly being estimated in professional circles. Grimm (2003) states as well that about 2% of children exhibiting language impairments should actually be regarded as ACA sufferers. Hécaen (1983) even

goes as far as to posit: „Aphasia is more frequent, at least among the youngest children, than in adults.” (ibid. p. 581).

In summary, concerning the evolution of aphasiology with regards to child-specific language impairments, the following can be ascertained: Starting with the earliest accounts of ACAs and up to the late 1970s, aphasiological research was concerned only with atypical manifestations of the clinical picture (cf. Guttmann 1942; Basser 1962; Alajouanine/Lhermitte 1965), or at least emphasized it in contrast to the heterogeneity of adult aphasia. Thus, ACA was primarily defined as nonfluent aphasia commonly occurring in confluence with lesions of the right hemisphere (cf. Paquier/Van Dongen 1998). On top of that, the notion of a swift and complete convalescence in ACA sufferers was purported for a long time (cf. Guttmann 1942; Basser 1962; Alajouanine/Lhermitte 1965; Lenneberg 1967; Hécœen 1976). Aphasia in adults and ACA were long distinguished by three main criteria: „(1) The children’s symptoms were said to be uniform and predominantly nonfluent, whatever the lesion localization; (2) Prognosis was assumed to be more favourable for children than for adults; (3) The frequency of right-hemisphere lesions was thought to be higher in children than in adults.” (Van Hout 1992, p. 139).

This perception of ACA has nonetheless shifted gradually since the late 1970s. Analogous to the research on aphasias in adults, there exist group studies (cf. Clarus 1874; Guttmann 1942; Alajouanine/Lhermitte 1965; etc.) as well as case studies (cf. Holland 1970; Lehecková 2004; Martins 2004 etc.). One singularly important medical innovation was the emergence of medical imaging, precipitating new insights regarding ACA. Employing computer-assisted tomography, Loonen and van Dongen (1990) determined the confinement of anomalies to the left hemisphere in the entire sample of aphasic children examined by them – a notion that had long been contested. Similarly, the techniques of PET, MRI and SPECT were more frequently employed over time (cf. Paquier/van Dongen 1998, Dennis 2010). Contrary to the established belief in the homogeneity of nonfluent ACA’s clinical picture, regardless of lesion location (cf. Guttmann 1942), these studies illustrate the correlation of lesions in various left-hemisphere regions with varying syndromes of aphasia (Paquier/van Dongen 1998).

SYMPTOMATOLOGY IN ACA

Dennis (2010) points out that children show a range of language disorders after acquired brain injuries and that language breakdown may occur at the level of pragmatics, semantics, syntax, morphology, phonology, or speech production. Thus, the clinical presentation of ACA affects all areas of language competence, just as it does with adult aphasia. In this context, it’s important to note that both forms of aphasia involve loss of language faculty and language comprehension based on cerebral organic causes, usually concomitant with retention of functionality in organs of speech, auditory perception and intelligence (cf. Kubandt 2009).

The traditional concept of ACA was primarily informed by the symptom of “nonfluency” as with Broca’s aphasia in adults (cf. Bernhardt 1885). This concept assigned five principal characteristic traits to ACA: Mutism, a period of hypospontaneity of speech, dysarthria, agrammatism and so-called “negative signs” (Van Hout 1992, p. 146). Negative signs, in this

case, are conceived as the absence of symptoms usually occurring in adult fluent aphasia, like jargon, logorrhea, paraphasia, neologism etc.

Traditional concepts regard **mutism** as one of the main symptoms of ACA. Branco-Lefèvre (1950) and Alajouanine and Lhermitte (1965) assumed a period of mutism ensuing immediately after the onset of an aphasic disorder. Likewise, Hécaen (1976) determined that such a period of mutism lasts far longer in ACA patients than it does in adults. He further stated a correlation between the type and location of cerebral injuries and the emergence of mutism. In this regard, von Cramon (1981) distinguishes between two different types of mutism: “true mutism” denotes the inability of expressing any sounds at all, while “word mutism” describes the inability of expressing oneself verbally resp. communicating (cf. *ibid.* p. 801ff). The term “aphasic mutism” is commonly used instead of “word mutism”, though it’s often difficult to distinguish from the so-called period of “**hypospontaneity of speech**” (cf. van Hout 1992, p. 146; Satz/Lewis 1993, p. 650f.), meaning a decrease in spontaneous speech, which often follows the period of mutism. This period usually lasts longer than mutism (cf. Satz/Lewis 1993). The symptomatology also encompasses a deficiency in initiating conversations. This phenomenon is rarely found in adult aphasic patients and is also considered as characteristic for ACA (cf. van Hout 1992). It is furthermore prevalent in young children. Van Hout and Seron (1983) regard the dysfunction of a speech “initiator” in connection with subcortical structures as the root cause of this symptom (*ibid.* p. 193). Spencer (2006) describes the decrease in spontaneous speech as a limitation and simplification of verbal behavior, as a depletion of vocabulary, as a reduced rate of speech and as a diminished mean length of utterances (MLU).

Deficiencies in the area of syntax have been an issue since ACA was first reported (cf. Bernhardt 1885) – however, there has not yet been enough research conducted in this field. Alajouanine and Lhermitte (1965) proceed on the assumption that syntax in aphasic children is characterized by simplification rather than deficiency, as is the case with aphasia in adults suffering from **agrammatism**. It is for this reason they state that “true agrammatism never occurs in children” (*ibid.* p. 658). Boehringer et al. (1979) too declared there to be no similarities to adult agrammatism. In contrast, Dennis (1980) assumes that agrammatism can very well occur in children and impair expressive as well as receptive capabilities. One problem in diagnosing agrammatism relates to the fact that due to mutism resp. reduction of spontaneous speech, the MLU in aphasic children often turns out to be rather sparse. This in turn exacerbates the effort of drawing conclusions with regards to syntactic abilities. On a lexical level, ACA sufferers display conspicuous problems in naming things (cf. Satz/Lewis 1993). In his 1983 studies, Hécaen observed lasting “naming disorders” in 44% of ACA cases with left-hemisphere lesions (cf. *ibid.* p. 58ff). Cases like this are commonly referred to as **anomies** (cf. Van Hout 1992; Satz/Lewis 1993). Moreover, the following is held to be true with regards to ACA-induced lexical disorders: “Lexical problems have been described as true anomia, reduced with the help of phonemic cues, or as a loss or poverty of vocabulary, more similar to a reduction of use or an impoverishment of the memory stock.” (Van Hout 1991, p. 118).

Concerning the existence of paraphasias, professional opinions differ. As well as disputing the existence of childhood agrammatism, Alajouanine and Lhermitte (1965) also deny the occurrence of paraphasias with regards to ACA, or at least emphasize its scarcity (cf. *ibid.* p. 658). Hécaen (1976) aligns himself with this notion. More recent studies however produce arguments for the existence of paraphasias (cf. Van Hout et al. 1985; Visch-

Brink/Van de Sandt-Koenderman 1984; Van Dongen/Visch-Brink 1988). They offer a possible explanation for the counterargument of scarcity by pointing out that paraphasias in conjunction with ACA mostly occur over only a short period of time and thus are more likely to be overlooked (cf. Satz/Lewis 1993). According to Aram (1991), paraphasias are much more likely to emerge in acute phases, but might also persist over a longer period of time. Spencer (2006) as well assumes that semantic and phonemic paraphasias present themselves primarily in the first few months following a child's impairment. Dennis and Barnes (1990) have shown that children with TBI have deficits in comprehension of mental state verbs as well. As mentioned earlier, traditional doctrine regarding ACA presupposed the existence of so-called "**negative signs**" until the end of the 1970s. The notion of these "negative signs", encompassing for example mutism, dysarthria, telegram style and a reduced length of sentences, led to a characterization of ACA as predominantly "non-fluent" (cf. Fabbro 2004). Guttmann (1942), Alajouanine and Lhermitte (1965) as well as Hécaen (1976) even assumed a complete absence of fluent aphasia in children. This traditional concept, however, has been amended by several studies conducted in recent years. In this context, Aram (1991) drew attention to the dearth of crucial information with regards to the language of aphasic children: "Very little systematic investigation of phonology or articulation has been pursued among children with acquired aphasia; the data are not available to generalize as to conditions that may relate to the presence or absence of phonological and/or articulatory problems." (ibid. p. 437).

Hécaen (1976) refers to impairments of **written language** as frequently occurring in ACA sufferers. According to Alajouanine and Lhermitte (1965), disorders of written language acquisition are generally encountered in the context of ACA and more prevalent than linguistic disorders. All three authors point out that ACA in conjunction with written language is far more likely to affect writing disorders than impairments in reading proficiency (cf. Alajouanine/Lhermitte 1965; Hécaen 1976). Spencer (2006) describes it as the worst possible partial prognosis, taking into consideration that reading and writing are the last acquired modalities of language acquisition. In this context however, Aram (1991) criticizes the lack of detailed reports and studies regarding written language proficiency in afflicted children. Even if it is less impaired than written language proficiency, reading proficiency is often significantly more dysfunctional than spoken language. On the other hand, Dennis (1980) was able to show by means of a study that while reading proficiency was much more impaired than language proficiency during the acute phase of affliction, those circumstances underwent a reversal over the course of three months. One has to bear in mind though that, according to Rother (2005), in the context of writing and reading dysfunctions are particularly noticeable if these skills were already acquired premorbidly (cf. ibid. p. 52). Some studies however show that children who have acquired aphasia at a pre-school age are faced with significant issues, meaning they either won't be able to learn how to read and write or merely on a very limited level (cf. Gloning/Hift 1979). In general, a correlation between the severity of written language impairment and the age of the afflicted children is hypothesized (cf. Rupp 2006). Thus, Hécaen (1976) observed deficiencies of written language in 90% of under-10-year-olds vs. only 45% of over-10-year-olds. Since younger children are still in the process of learning written language, they often display more severe difficulties. Aram (1991) too emphasizes how skills that have yet to be acquired are more susceptible to dysfunctions than those premorbidly existent. These cases are further aggravated by the difficulties in performing a differential diagnosis between aphasia and dyslexia, especially if the aphasia

hasn't been recognized as such and the corresponding symptoms only appear years after the acquired cerebral impairment. All told, what can be established is that recent studies indicate a variety of different reading and writing dysfunctions as possible effects of ACA, comparable to those experienced by adult acquired aphasia sufferers (cf. Loew/Böhringer 2002, p. 23).

Utilizing new techniques and improving upon existing neurolinguistic testing procedures, it has now become possible to examine highly diverse aspects of language more accurately. Procedures such as these made it feasible to establish "**positive symptoms**", like **logorrhea**, **paraphasias**, **perseverations** and **neologisms**, alongside the previously mentioned negative symptoms (cf. Fabbro 2004; Lehecková 2004; Paquier et al. 2004): "Recent case studies show a great variety of aphasic symptomatologies including auditory comprehension disorders, paraphasias, neologisms, logorrhea, jargon, impaired repetition abilities, and a host of linguistic deficits in reading and writing." (Paquier/van Dongen 1996, p. 428).

Thus, nowadays it has become basically assumed that all symptoms occurring in adults might also be found in children (cf. Van Hout/Evrard/Lyon 1985; Martins/Ferro 1991; Fabbro 2004; Lehecková 2004; Paquier et al. 2004; Rother 2005).

Compared to the vigorous efforts in classifying the various aphasic dysfunctions in adults however, there have been markedly fewer corresponding attempts with regards to ACA. Aside from classification in terms of etiology, lesion locus and manner of spontaneous language, ACA used to always be described and categorized via its symptoms (cf. among others Van Hout 1992): "The aphasic symptoms in children are not as differentiated with respect to location as in the adult." (Tartter 1998 p. 223; also cf. Goodglass 1980). One of the most current works on ACA, "Neurogenic Language Disorders in Children" (2004), edited by Franco Fabbro, nonetheless asserts that all adult-specific aphasic syndromes can also occur in children: "Moreover, these symptoms correlate with clinical aphasic profiles and lesion localizations similar to those of adults. Indeed, at least in their acute phase and lesional phase aphasic syndromes in children have been found similar to most of the aphasic syndromes in adults." (Fabbro 2004, p. 2). Likewise, Van Hout (1992) and Van Dongen et al. (2001) refer to the "existence of an adult-like heterogeneity of childhood aphasic syndromes." (ibid. p. 345). In this regard however, Van Hout (1992, 1993) points out that although aphasic symptoms in children have been found to be similar to those of adults, children may show atypical symptoms. Among professionals, this is considered status quo as far as the symptoms of ACA are concerned.

SYMPTOMS ASSOCIATED WITH ACA

Aside from aphasia, several other attendant symptoms may occur, among them for example hemiplegia, epilepsies, dysphagia and disorders of concentration, attention and memory (cf. Franke 2004). Hécaen (1976) and Leischner (1987) for example observed a high number of hemipareses in aphasic children. According to Spencer (2006), damage to the frontal lobe as a common result of traumatic brain injury can lead to attention disorders and disorders of the working memory in aphasic children, as the frontal lobe is host to these neuropsychological functions. In the context of ACA, Miller et al. (1984) address other characteristic traits not directly attributable to the aphasia. They determined that ACA often

goes hand in hand with comprehension issues and note, among other things, that afflicted children oftentimes appear deaf-like and also act accordingly. Guttmann (1942) and Agranowitz/McKeown (1975) have also drawn attention to this particular aspect of ACA. Rothenberger (1986) observes that cognitive, motoric and emotional issues are possible byproducts of aphasia. Sollee and Kindlon (1987) see a correlation between cerebral lesions and behavioral problems in children, thereby corroborating studies conducted by Herzberg and Herzberg (1977). Campbell and Heaton (1978) too refer to behavioral disorders. To them, this includes diminished attention, aggression, temporary outbursts and, in some cases, hyperactivity. Agranowitz and McKeown (1975) also describe these phenomena and state: "Behavior problems play an important part in the diagnosis of aphasic children." (*ibid.* p. 192). Dennis and Levin (2004) discuss the behavioral outcome after TBI too. Mantovani and Landau (1980) suspect that behavioral disorders in connection with ACA "may reflect a primary disinhibition at limbic or diencephalic levels." (*ibid.* p. 528). In contrast, Miller et al. (1984) would sooner ascribe the behavioral problems to the sudden loss of speech and look towards psychological reasons as root causes. The studies of Campbell and Heaton (1978) also speak for the validity of the latter explanation. Their thesis is based on the observation that behavioral disorders tend to disappear once the afflicted children are presented with alternative systems of communication.

Furthermore, a syndrome often mentioned in context of ACA is the so called Landau-Kleffner-Syndrom. Bishop (1985) describes it as a "syndrome of acquired aphasia with convulsive disorder, in which language regresses after a period of normal development and seizure develop" (*ibid.* p. 705).

PROGRESSION, PROGNOSIS AND OUTCOME

Dennis and Barnes (1990) state that "the bases for language symptom patterns and recovery rates in children and adolescents with acquired lesions are poorly understood" (*ibid.* p. 429). Concerning recovery and linguistic capabilities of ACA sufferers, a marked variance in prognosis and progression is held to be true. The primary factors being recognized in connection with recovery are type of injury and age of the child at the lesion's onset (*cf.* Aram 1991). Progression of ACA has almost exclusively been characterized in relation to the question of prognosis. Despite numerous studies, the long-term development of ACA still remains ambiguous (*cf.* Miller et al. 1984). The traditional view of ACA proceeded from the assumption of an excellent prognosis, especially when compared to adult aphasia (*cf.* Clarus 1874; Bernhardt 1885; Freud 1897). This traditional notion endured over the course of the 20th century (*cf.* Guttmann 1942; Alajouanine/Lhermitte 1965; Lenneberg 1972; Hécaen 1976). The researchers arrived at this conclusion by way of the long-held assumption that aphasic symptoms in children were merely temporary and rarely persistent. In his study, Guttmann (1942) recounts astonishingly positive prognoses in some cases: "The recovery from aphasia of the purely motor type is surprisingly rapid, and most cases with a reversible lesion have recovered within four weeks." (*ibid.* p. 218).

More recent papers and studies on the topic contradict this hypothesis at least to some extent. For example, Satz and Bullard-Bates (1981) analyzed data on ACA that had been published up to 1978 and pointed out that 25 to 50% of cases were still suffering from aphasia

a year after onset of the disorder. Loonen and Van Dongen (1990) observed comparable cases: "Most of the children had not recovered completely 1 year after onset." (ibid. p. 1324). Jordan and Murdoch (1994) examined a number of adults who had suffered severe head injuries during childhood and reached a similar conclusion: "Results indicated that all areas of language competence assessed (syntax, semantics, and pragmatics) appeared to be compromised by the childhood closed-head injury." (ibid. p. 506). Two years later, Jordan and Ashton (1996) published a similar study with a subject group comprised of children and arrived at the same results.

One possible explanation for these recent insights and notions may well be that earlier studies had either neglected to account for variables that could possibly affect the prognosis or had merely considered them in a fleeting manner. Van Hout (1991) criticizes the long-held belief of age being the main criterion for a good prognosis. She counts etiology, age at the time of onset, lesion scale and types of aphasia among the variables far more important for arriving at a prognosis. The differing etiologies of ACA render it nigh impossible to reach a universally valid assessment. The factor of differing etiologies being mostly disregarded might be explained by the long-held notion of childhood aphasia as relatively homogeneous phenomena. Van Dongen and Loonen (1977) were among the first to ascribe vital importance to etiology with regards to prognosis. Among other things, they reached the conclusion that ACAs stemming from cerebral traumata will often recover completely (cf. ibid. p. 135f). Moreover, they argued in favor of the prognosis of traumatically induced aphasia being much better than of those stemming from inflammatory processes. Niedergall and Renschmidt (1981) share this opinion. Dennis and Barnes (1990) state that "recovery of speech and language in instances of childhood head trauma is overall better than recovery from some other acquired conditions of childhood" (ibid. p. 429). Martins and Ferro (1991) however arrive at this conclusion: "[The] children with stroke had a very good recovery compared to those with traumata and especially the infectious cases." (ibid. p. 179). Dennis and Barnes (1990) conclude that "not all clinical language functions return after head injury. And even after clinical recovery of language, the question remains how effectively the individual can use language for social and interpersonal communication, a question that concerns not clinical language functions (naming, repetition, fluency, and the like), but discourse." (ibid. p. 429). A different case study of Martins (2004) based on fifty ACA patients indicates that in 11 cases, the patients were still suffering from chronic aphasia two years later. She thus concludes that it's not factors like age or gender that are of relevancy to the recovery process, but rather factors related to the scale and location of the lesion. One difference between ACA and aphasia in adults is the time of improvement, according to Martins: "Curves of aphasia recovery in adults (again, mostly stroke patients) have shown that the greatest improvement is seen in the first 3 months (especially in the first three weeks)... There may be some recovery during the first year..., but afterwards there are no significant changes, and functional decline has occasionally been reported... Although children who recovered did so during the first year, in our group of chronic aphasia improvement of different language abilities was found not only after the first year, but also 5 or more years after lesion onset, causing changes in the aphasic profile and taxonomic diagnosis." (ibid. p. 245). According to Martins, another fundamental difference with regards to adult aphasia's recovery lies in the fact that with children, language performances were far more likely to improve even in the chronic period: "Regarding recovery, there are two main differences between these findings and findings related to adult aphasia. First, unlike adults,

the overall recovery was better in children and, secondly, children improved in the chronic period.” (ibid. p. 245). Martins argues in favor of a better prognosis for ACA versus adult aphasia in general, yet criticizes the lack of knowledge regarding cases of chronic aphasia. Lehecková (2004) arrives at a similar conclusion. By contrasting the recovery of a Czech child suffering from aphasia with that of an adult aphasia patient, she reasons thusly: “The child’s aphasia is basically manifested in the same way as the adult’s aphasia with one exception: while the adult patient two years post-onset reached a stage after which her language skills no longer improved, the child has continued to develop her linguistic abilities.” (ibid. p. 227f).

All told, it is notable that ACA prognosis is not regarded as positively today as it once was, especially compared to adult aphasia. Factors like age and gender have taken a backseat to etiological factors.

Nevertheless, more recent studies demonstrate that even with existing resp. chronic aphasia, there is still the possibility of successful recoveries, especially in children. A number of authors attribute this fact to the brain’s plasticity during childhood (cf. Becker et al. 1986; Loew/Böhringer 2002, Fabbro 2004). Even in this context however, the prognosis is not estimated as positively anymore as traditional notions once held (cf. Kubandt/Friede 2011).

In this context, one aspect that is left unconsidered by ACA research is the fact that in some cases, aphasic symptoms can still emerge long after the acute event and subsequently remain unrecognized. This could possibly be one cause of childhood and adolescence aphasia not being diagnosed (cf. Kubandt 2008a, 2009). Benz and Ritz (2003) thus call attention to the no longer applicable traditional adage positing that, due to the brain’s plasticity, the long-term effects of TBI are significantly more favorable the younger a child is at the time of the accident. The authors argue that children actually tend to grow into their permanent deficit. Another aspect to consider with the so called phenomenon of ‘growing into deficit’ is the fact that afflicted children often experience retardation of further development. This results in a progressive ability gap when compared to their peers, one that subsists even in the face of continuous development. The issue has long been neglected and disregarded. In this context, the prognosis for ACA sufferers is negative insofar, as the afflicted need to both reacquire the abilities they have lost due to cerebral injuries as well as develop additional abilities to advance their overall progress. This in turn necessitates repeated examinations to supervise further progression following the accident or onset of disease (cf. Kubandt 2009).

All in all, and analogous to adult aphasia, ACA is not without consequences. Aside from the symptomatic impairments already mentioned, there are also **psycho-social consequences** to contend with. Unfortunately, this is another area that has so far been rather neglected by ACA research (cf. Kubandt 2008a). This leads Martins (2004) to emphasize the negative consequences of ACA in spite of its overall supposedly better prognosis compared to adult aphasia: “Although chronic aphasia tends to have mild forms of aphasia and their linguistic abilities may continue to improve in the chronic stage, persistent aphasia has a negative impact on their educational, social and professional life.” (ibid. p. 247). The three mentioned aspects also play a vital part in the context of therapeutic interventions.

To summarize the phenomenon of ACA it can be referred to a definition by Brown and Hécaen (1976):

“1. Acquired childhood aphasia is characterized by mutism or agrammatism at an early age, and by anomia and nonfluent phonemic paraphasias somewhat later. 2. Articulatory

disorders in acquired childhood aphasia appear in the context of a nonfluent or borderline fluent state. 3. The picture of fluent phonemic paraphasias in conversation (conduction aphasia) is rarely encountered. 4. Logorrhea and semantic or neologistic jargon do not occur in acquired childhood aphasia. 5. Disorders of comprehension are present in about one-third of the patients, but the adult-type correspondence between comprehension loss and logorrheic jargon is not found. 6. Recovery tends to be superior to recovery in adult aphasia. 7. At any early age, there is a relatively even chance that aphasia will occur with injury to either hemisphere.” (ibid. p. 189).

PROSPECTS OF INTERVENTION REGARDING ACA

The area of clinical intervention is highly significant to people suffering from aphasia as well as their family members. There exists a wealth of research regarding diagnostics and therapy for adult aphasics. Just as in all other respects, aphasiology targeted towards children has, however, taken a clear backseat to adult-specific aphasiology. Instead, diagnostic and therapeutic tools designed with adults in mind are also employed with ACA, without ever having been empirically proven as beneficial (cf. Kubandt/Friede 2011). Within the fields of diagnostics and therapy, two main trends are predominant: Cognitive neurolinguistic on the one hand, offering a possible foundation for precisely structured and scientifically valid diagnostics and therapy; and, on the other hand, a pragmatic-communicative approach mainly allowing for diagnostic as well as therapeutic procedures in the context of communicative agency and daily routine (cf. Kubandt 2008a). Even today, literature on ACA very rarely references diagnostics and therapy. Seeking a similar range of diagnostic options and techniques as is typically on offer for adult aphasias proves to be a fruitless endeavor.

DIAGNOSTICS

Guttmann (1942) was among the first researchers to draw attention to the inherent difficulty in diagnosing ACA. Numerous cases remain undetected, which Guttmann regards as a reason for the general assumption of low prevalence. His definition of ACA posits the disease not as a rare occurrence, but rather as a seldom recognized clinical picture. Agranowitz and McKeown (1975) characterize these undiagnosed childhood aphasias as the single most serious issue for those persons affected by them.

Diagnostics in general aim to obtain as comprehensive an impression as possible of a child’s linguistic abilities to use as a springboard for further therapeutic steps. This includes assessment of the pre-morbidly achieved level of speech (cf. Loew/Böhringer 2002, p. 29). On one hand, this assessment is necessary in children with acquired cerebral injuries in order to differentiate between a language impairment and ACA; on the other hand, it offers hints as to therapeutic strategies and their objectives. Furthermore, the pre-morbid level of speech (among other factors) can also offer indications concerning progression and prognosis. However, Becker, Bergmann and Kubiak (1986) emphasize that aphasic impairment may well be the most prominent symptom in children and adolescents, but hardly the only one. The cerebral injury negatively impacts the child’s entire personality (ibid. p. 59). It is for this

reason they call for examinations to assess a child's entire personality instead of merely cataloguing its linguistic abnormalities.

Practice has proved the usefulness of gathering essential information regarding the pre-morbid level of speech by way of initiating a dialogue with the parents and having them fill out questionnaires, as well as gaining access to school reports (cf. Kubandt 2008b). The checklist of diagnostics developed by Bulling, Geigenberger and Hofman (2002) can serve as one possible example of such a questionnaire. In it, questions regarding manners of speech and communication both pre- and post-onset are posed. In order to examine motor speech, screenings for apraxia of speech and dysarthria may be employed (cf. Loew/Böhringer 2002; Spencer 2006). Yet another aim of diagnostics is assessing the progression of the disease. Findings and information supplied by prior attending facilities and specialists, like rehab clinics, schools, physicians, neurologists and speech therapists for example, as well as statements from relatives, allow for more specific diagnostics. Information such as this is especially vital in diagnosing illusory recovered aphasias (cf. Chilosi et al. 2008). Beyond that, Loew and Böhringer (2002) regard the assessment of a child's current need for communication as an important diagnostic goal. Yet another aspect figuring into the issue of diagnostics is the assessment of other neuropsychological abilities - attentiveness and perceptiveness, for example. Becker, Bergmann and Kubiak (1986) point to the importance of not merely using the diagnosis to assess the impaired abilities and performances of the afflicted children, but above all those a child is still in possession of, since these serve as a gateway to rehabilitation (ibid. p. 59).

THERAPY IN APHASIC CHILDREN

With regards to therapy in aphasic children, there is much research still to be done, especially in direct comparison to the wealth of available therapeutic approaches and techniques for adult aphasia (cf. Kubandt 2009). Becker et al. (1986) cite rehabilitation of the linguistic abilities possessed by the child pre-insult as an integral task of therapy, as well as the acquisition of new linguistic skills (like written language skills, for example), since the latter usually poses considerable difficulties to the afflicted children (ibid. p. 63). They denote the exceptionality of ACA therapy vs. therapy for adult aphasia thusly: the conjunction of practices acting towards the recovery and acquisition of linguistic skills during an individually aggravated learning process (ibid.). Eisenson and Ingram (1972) consider it of vital importance to diagnostically assess a child's pre-morbid level of linguistic development before the start of therapy, the former serving as a starting point for the latter. Therein lies a fundamental difference to rehabilitation in adults: While adult aphasia patients' therapy is geared mainly towards recovery of pre-existing skills, children are obligated to undergo further development in all respects, be it motorically, linguistically, socially or cognitively. Thus, it is not enough to merely relearn pre-morbidly existent skills. Consequently, the focal point of rehabilitation, in addition to the *reclamation* of pre-existent skills, is stimulating a child's capacity *to learn something new*. Both of these aspects are of central importance in ACA therapy and should be borne in mind.

WORK WITH PARENTS

Relatives should receive information about the clinical picture of aphasia and act as significant support systems during therapy (cf. Becker et al. 1986; Spencer 2006): “Parents of the aphasic child are usually confused and baffled by the many problems confronting them.” (Agranowitz/McKeown 1975, p. 196). This has the effect of further elevating the importance of working with parents in the context of therapy – not only to assist affected parents and siblings, but also the afflicted children themselves. Especially where aftereffects, like for example behavioral disorders, are concerned, educating parents resp. relatives becomes a substantial aspect of therapy: “The parents need to understand the basis of their child’s behavior. Most of the symptoms are directly related to the brain injury and must be understood as part of the picture of the aphasic child.” (Agranowitz/McKeown 1975, p. 197). There should be parent counseling with regards to possibilities of the child’s reintegration at school and the most advantageous course of education (cf. Kubandt 2008a, Kubandt 2009). Therefore, working with parents is regarded as a central aspect of the therapeutic process by all the authors. In this respect, Becker et al. (1986) consider both one-on-one conversations and parent group discussions as useful tools to be employed regularly in addition to a child’s therapy. Agranowitz and McKeown (1975) recommend parent groups as a medium of reciprocal communication and support. Roberts (1966) likewise regards working with parents a fundamental pillar of therapy. Hahn et al. (2002) too conducted regular meetings with parents during the course of therapy in order to provide transparency and point out support options to them. They consider it just as relevant to create a setting for potential questions and issues on the parents’ part and stressed the need to impart advice for dealing with a speech-impaired child (ibid. p. 50). The aims of meeting with parents outlined above are generally acknowledged as being sensible and should be considered for comprehensive use in therapy.

SCHOOL REINTEGRATION OF APHASIC CHILDREN AND ADOLESCENTS

A general question within the context of young patients’ aphasia therapy is the one concerning their continued school career. The ICF’s conception of target objectives in particular places the individual in its entirety in the centre of the rehabilitative process and regards scholastic and occupational rehabilitation as worthy goals in addition to medical rehabilitation. Becker et al. (1986) therefore recommend a therapeutic course of action within small groups of children, regarding it as preparation for an eventual rehabilitation of the aphasic child into the school system. Roberts (1966) and Haynes (1986) also recommend group-centric therapeutic measures.

The question of further scholastic development is of vital importance with regards to ACA, yet still remains sparsely researched (cf. Kubandt 2009), just like every other field of child-oriented aphasiology. Agranowitz and McKeown (1975) are among the few to have focused on this subject. They note that school should be adjusted towards the children’s needs: “the aphasic child learns better in a situation with minimal stimulation.” (ibid. p. 194). Another of the few publications on this topic originates from Girolami-Boulinier (1986) and addresses the scholastic development of children and adolescents in the Paris area. However, Girolami-Boulinier himself notes that this should by no means be considered a representative

study. Its results are as follows: From the perspective of school education, a return to the past school system route is important (with or without delay). If an adolescent has not reacquired this former level after 1.5 to 2 years, it becomes necessary to detect possibilities of directing him towards an apprenticeship that actually corresponds with his interests, so his acquired skills won't deteriorate anew (ibid. p. 85). Admittedly, reintegration into regular school is often impossible since overly large grades and time pressure due to curricula do not allow for catering to the individual needs of impaired children. Hofmann Stocker (1991) determined by way of a study that of 23 adolescents suffering from aphasia, only half were able to resume their education. It is for this reason Birkenbeil (1995), in marked contrast to Girolami-Boulinier (1986), calls for specially tailored types of schools. In general, the question of school rehabilitation still remains insufficiently researched, with many problems left unsolved and many questions unanswered (cf. Kubandt 2008b, Kubandt 2009).

CONCLUSION

Regarding the field of aphasia research in the context of ACA, there's an evident future need for increased attention and efforts. A pivotal research gap concerns the field of diagnostics and therapeutic studies. The necessity of speech therapy is undisputed, yet there are no particular standardized testing procedures and therapy programs available, creating a rather significant need for further research. A particular problem in this regard is posed by issues of quality assurance, efficiency and effectiveness of diagnostics and therapy. At the present time, both diagnostics and therapy run the risk of arbitrariness. Means of interventions regarding ACA that are based on adult aphasiology pose the danger of outdated and heavily criticized approaches and materials being adopted for the purpose of children- and adolescent-oriented intervention, unreflecting and without regard for the criticisms voiced by researchers. At a time evidence-based rehabilitation is at the centre of debates, this seems problematic and academically untenable.

Regarding the demonstrated particularities of prognosticating ACA, the ultimate conclusion is to commence with the rehabilitation process of aphasic children and adolescents as soon as possible (i.e., directly following the acute clinical treatment) and to allow for a sufficient period of time. Furthermore, the process should be comprehensive, including medical measures as well as those with the purpose of scholastic, occupational and psychosocial rehabilitation.

Chapter 88

APHASIA IN CHILDREN AND ITS IMPACT ON QUALITY OF LIFE

Michitaka Funayama¹, MD and Asuka Nakajima², MSc, RST

²Department of Rehabilitation, Ashikaga Red Cross Hospital, Ashikaga, Japan

ABSTRACT

People who develop aphasia must adjust their lifestyle and learn to cope with the activity limitations that result from their disability. Aphasia can profoundly affect a person's capacity for academic achievement as well as their occupational competency, social participation, and ability to manage finances. This is especially true for young people, who have yet to fully learn how to participate as a member of society. Young people who acquire aphasia are likely to have a poor record at school and have difficulties completing higher education and getting a job. They also might be unable to pass a written test for a driver's license. Young people with aphasia who wish to contribute to the community and be engaged in social activities might not achieve these goals and might feel isolated. In the worst case, they might shut other people out of their lives and withdraw from society. In this chapter, we describe the long-term prognosis of three individuals who became aphasic in their childhood or youth and discuss how young people with aphasia can best be rehabilitated.

1. INTRODUCTION

The first verse in the Gospel of John reads, "In the beginning was the Word, and the Word was with God, and the Word was God." It is quite difficult to live without the Word. Language ability is usually taken for granted—until it is lost. Brain damage can cause aphasia and affect a wide range of language abilities including the understanding of speech, talking, reading, and writing. One can have an experience close to aphasia when visiting a foreign country where one is unable to understand others' language and unable to converse with

others. However, aphasia differs from this scenario because a person with aphasia also experiences difficulty in thinking in their own language.

Aphasia can result from any type of brain damage, including stroke, traumatic brain injury, brain tumor, and infection. Approximately 30% of first-ever ischemic stroke survivors have aphasia (Engelter et al., 2006). For the person with aphasia, sudden changes in language processing immediately impact daily communication and change the nature of communicative exchanges and the quality of interactions. Although people with aphasia want to function as they have in the past, they often are unable to work and are confronted with an enormous challenge to fulfill their roles in daily living—for example as a partner, parent, or friend. Some might even develop depression (Astrome et al., 1993), which often is related to loneliness, isolation, low self-esteem, and the inability to accept themselves as a handicapped person.

Although aphasia occurs most commonly in the latter half of life, some individuals may acquire aphasia in childhood. In these cases, aphasia greatly affects the whole life.

Despite the challenges that they face, people with aphasia generally wish to be engaged, involved, and respected, to take part in the community, to be cognizant of current events, to do things with others without being a burden, to contribute to the community, and to generally carry out a daily routine. In this chapter, we describe three young people with aphasia and review the impact of aphasia on these individuals. We also discuss how to rehabilitate children with aphasia.

2. CASE PRESENTATION

Case Presentation 1

Case 1 was a 17-year-old high school student when he experienced a brain hemorrhage attributable to arteriovenous malformation. He was admitted to a hospital in his town with disturbance of consciousness. Computed tomography revealed the location of the lesion in the left temporal lobe which covered Wernicke's area and its underlying white matter, the arcuate fasciculus, which both play a critical role in linguistic functions. Surgical resection improved the disturbance of consciousness, but aphasia remained.

The aphasia was classified moderate-severity Wernicke's aphasia with poor auditory processing, fluent speech, and poor repetition. Owing to poor auditory processing, the patient had difficulty understanding others' speech. Although he spoke fluently in sentences, the content of those sentences sometimes contained verbal paraphasias as well as phonological paraphasias. Repetition was limited to a few phrases. An intensive aphasia treatment program was provided in the hospital, and the Wernicke's aphasia improved to some extent. After treatment, however, the patient still had difficulties understanding long sentences, talking, sending text messages, and learning. In contrast, he had relatively intact nonlinguistic cognitive skills, such as memory and visuospatial function.

Prior to his hemorrhage, the patient had an average school record and was a polite and friendly young man. However, he could no longer participate in the things he enjoyed such as studying at school, talking with friends, and sending text messages to friends. He was unable to pass a written driver's test and therefore could not obtain a driver's license. He gradually

began to lose contact with friends and spent more time indoors enjoying computer games or reading cartoons. After graduating high school, even though he tried to work in several factories, he quit each job after a short time because he was not able to communicate well with others. He could not fully manage his finances. At 9 years post-onset, case 1 has become socially isolated.

Case Presentation 2

Case 2 was an 18-year-old high school student when he was riding his bicycle home from school and was struck by a truck. In the hospital, he was in a deep coma (Glasgow Coma Scale score 5; E1V1M3). He was intubated and mechanically ventilated. Brain computed tomography revealed left fronto-temporo-parietal hemorrhagic contusions with midline shift, which required hematoma resection as well as internal and external decompression. After 10 weeks, the patient regained consciousness and participated in neurologic rehabilitation therapy. After 6 months of therapy, he was discharged with right complete hemiparesis, total aphasia, severe apathy, and attentional dysfunction. His follow-up computed tomography at 1-year post-onset revealed brain damage that covered almost all of the left hemisphere.

The patient had global aphasia, presenting with impairment of all productive and receptive linguistic functions, which was resistant to intensive speech therapy provided in the hospital. He was unable to produce any spontaneous speech. Repetition was also totally impaired in that he could not repeat even one word. Comprehension was poor even on a word level, and he was unable to understand sentences. Comprehension of written language was also severely impaired. Communication was partly possible with the aid of non-verbal gestures. He was totally unable to manage his finances.

In summary, the communication capabilities of case 2 were extremely poor and were limited to very simple words and non-verbal gestures. The patient dropped out of high school and could not get a driver's license. He was incapable of meaningful social engagement and thus gradually lost contact with friends and often stayed indoors. Seizure control was difficult, and in the 10 years following the injury the patient had to be hospitalized several times owing to status epilepticus. At 10 years post-onset, the patient's activities were limited to going to rehabilitation four times per week for physical and linguistic improvement.

Case Presentation 3

Case 3 was a 13-year-old junior high school student when he fell from a height of 6 meters. He was in a deep coma when he arrived at the emergency department of our hospital. His traumatic brain injuries required internal and external decompression. His coma subsided, and he was discharged at 6 months post-onset. Follow-up computed tomography performed at 1-year post-onset showed damage of the left temporo-parietal cortices and the right temporal pole.

The patient had moderate-severity Wernicke's aphasia. He also presented with attentional dysfunction and executive dysfunction. Although he returned to school at 1-year post-onset, his performance was substantially poorer than his pre-accident level. He could not fully understand what his teachers were saying. His ability to perform mathematical calculations

was severely compromised, and he was no longer able to perform simple additions of one figure that included carrying. He could not write some Kanji characters (Chinese characters) that are taught in the lower grades of primary school. He moved from a regular class into a special education class for handicapped children. After graduating junior high school, he entered a special support school for handicapped children where he was taught manufacturing technology, and he now hopes to get a job in a small workshop. He is unlikely to obtain driver's license because of his aphasia and attentional dysfunction.

Summary of the Three Young People with Aphasia

All three cases experienced problems with learning, vocation, driving, social communication, and making friends. Participating in society and making an optimal choice regarding vocation were the most substantive challenges during their rehabilitation.

3. IMPACT OF APHASIA ON DAILY LIVING

Aphasia negatively affects a wide range of activities, including classroom participation, vocation, driving, social participation, and managing finances.

A. Classroom Participation

As exemplified in the case presentations above, when children with aphasia return to school, they find it difficult to learn because, for almost all subjects, learning requires linguistic abilities. Children with aphasia achieve much less than expected, and their record at school is poor relative to pre-aphasia levels.

Very often, the problems observed in the classroom setting also include difficulties with interpersonal relationships. Those patients who are overly sensitive may interpret pressure, teasing, or joking as personal attacks. Children with aphasia are likely to have fewer chances to have a boy/girlfriend. Sometimes, they are encouraged to move from a regular class into a special education class or a special support school for handicapped children.

B. Vocation

Most people with aphasia stop working shortly after aphasia onset. However, the long-term employment status of children with aphasia has not been studied. Nonetheless, several studies have addressed long-term employment status of adults with aphasia. Parr et al., (1997) studied vocational problems of 50 adults with chronic aphasia. All subjects were aged 26–92 years and were 5–15 years post-onset. The employment rate was approximately 15%, and only one of those working had returned to a level of productivity equivalent to that of pre-aphasia employment. Hinkley et al., (1998) found that, of 31 participants with stroke-induced chronic aphasia between the ages of 23 and 69 years, all of whom had been employed at the

time of stroke, only 26% had returned to some level of employment, and none exhibited pre-stroke productivity. Thus, only a limited proportion of adults with aphasia seem to be able to work.

The severity of aphasia does not necessarily relate to return to work (Hinkley et al., 2002). In addition to the severity of aphasia, factors that contribute to good vocational outcome include workplace flexibility, social support, motivation, level of cognition, and level of motor impairment (Hinkley et al., 2002). Demographic factors such as age, gender, and education might also influence the ability to return to work, although these factors have not been sufficiently addressed. The Hinkley et al., (1998) study suggests that, in addition to the challenges associated with the severity of aphasia, both psychosocial issues and physical/neuropsychological functions play a critical role in a patient's ability to return to work.

Adults with aphasia who return to work with their previous employer often perform simpler types of work, whereas others have to change job because the previous job was simply too demanding. The most common difficulties in returning to work were related to job status and unwillingness to accept a position of lesser prestige even if it was necessitated by their disabilities.

There is an additional vocation-related problem for children with aphasia, and it relates to making a vocational choice. Vocational tests often require linguistic abilities and are therefore challenging for young people with aphasia. However, these young people often do not accept the more menial types of jobs suggested on the basis of vocational testing and might resent their family's efforts in arranging these jobs. Psychological and psychosocial issues should be carefully addressed before making a vocational choice.

C. Driving

Driving is a big issue for children with aphasia. In Japan, adults with aphasia who had already obtained a driver's license prior to their illness are required to get a doctor's permission to resume driving. They are able to resume driving when they are at a very low risk of seizures, have no visual or visuospatial problems, and have no attention dysfunction. Resuming driving is an important part of recovery. However, young people with aphasia have to pass a written exam to obtain their driver's license, which is highly challenging. For people with aphasia who do not drive, other transportation might also be difficult because of the requirement of buying a ticket, making a transfer, or following instructions.

D. Social Participation

People with aphasia tend to withdraw from interpersonal relationships and have small social networks. They are unable to take part in a conversation because they miss information or do not understand what has been said. Some affected individuals report a lack of symmetry in communication, and conversations tend to be one sided. Often, people with aphasia take a passive and predominantly listening role in group interactions and conversations. They feel alone even though they are with other people. Some people with aphasia feel they are a burden to others and therefore stop participating in social activities.

For most people with aphasia, the number of friends decreases after the onset of aphasia. Friends stay away because they do not know how to communicate with affected individuals, and as time passes it becomes more difficult for such individuals to make contact with others. Furthermore, making new friends is quite challenging. According to Hilari et al., 2006, 30% of people with aphasia indicated that they had no friends at 1 year or more post-onset of aphasia.

Davidson et al., (2008) studied this issue by observing how many people communicated with patients during the 240 hours of observation period. They reported that people with aphasia ($n = 15$) communicated with only 3 strangers and with 111 acquaintances, whereas age-matched people without aphasia ($n = 15$) communicated with 21 strangers and 220 acquaintances.

None of the people with aphasia visited friends during the observation period, whereas the age-matched people without aphasia visited a variety of places. Typical communications for people with aphasia included greeting friends at a stroke group meeting or respite center and brief conversations with friends who visited the affected individual's home, whereas typical communications for people without aphasia included extended discussions with friends and visiting and conversing with friends in their homes.

It can often be valuable to meet others with aphasia at an aphasia group. This can give persons with aphasia a sense of solidarity and make them aware that they are not alone in their affliction.

E. Managing Finances

Persons with aphasia are often unable to manage their finances independently and need assistance in budgeting. Some even require complete supervision of their funds and can sometimes express extreme frustration concerning their inability to be more involved in financial arrangements. People with aphasia often are eligible to receive a national pension in Japan; however, they may be unable to follow the procedures required to obtain this. For adults who became aphasic in childhood, managing finances can be quite difficult because most had not had any substantive experience with finances prior to the onset of aphasia.

4. REHABILITATION

Linguistic rehabilitation is provided by speech therapists. Unlike physical rehabilitation, aphasia continues to improve for many years after onset. This is especially true for young people with aphasia, some of who might experience improvement for more than a decade. The optimal rehabilitation strategy varies from person to person depending on the type of linguistic dysfunctions that are present, e.g., apraxia of speech, dysprosody, phonological impairments, and comprehension deficits. Rehabilitation aims to help patients regain communicative function to participate in activities of daily living.

A. Communication Methods

In cases of severe aphasia, communication can be accomplished nonverbally, e.g., by drawing, facial expressions, head shaking, nodding, laughter, crying, counting on fingers, pointing with hands, and gestures including rudimentary pantomime. Simple visual analog rating scales are useful to obtain information about how the person with aphasia is feeling, e.g., presenting the patient with 10 faces with expressions ranging from unhappy (1) to happy (10) and asking them to choose a face (Davidson et al., 2006). Making use of communication books or cards in which personal information is included can also facilitate conversation.

B. Communication Partners

Some caregivers have limited knowledge of aphasia whereas others have the skills required for effective communication with aphasia patients. Family members can greatly influence a patient's progress in rehabilitation. Some family members have the tendency to overprotect, excluding the aphasic individual from making decisions, whereas others are successful at promoting the individual's abilities. Family members and friends often do not know how to communicate with people with aphasia, and thus they must depend on a speech therapist to act as a bridge between patients and family members/friends.

Typical communication skills that are effective when communicating with people with aphasia include asking closed questions, taking a speaking pause when needed, and using short sentences. If an individual with aphasia lives with people who have the knowledge and skills to adapt to the communicative limitations of the affected individual, they have a better chance of achieving social engagement.

C. Personal Factors

Physical and neuropsychological factors affect the rehabilitation process. Some people with aphasia are confronted with physical impairments that restrict their ability to engage in routine activities. These impairments may include palsy, chronic pain, poor balance, epilepsy, and fatigue.

Neuropsychological factors that can affect rehabilitation include apathy, executive dysfunctions, and deficits in memory, attention span, and concentration. The more severe or numerous these conditions, the less the patient will be able to communicate socially. However, people with aphasia, even severe aphasia, can engage in activities that involve predominantly nonverbal functions, such as playing cards, drawing pictures, taking photos, and gardening, and can playing sports—if they have no palsy. These activities increase the sense of feeling connected with others.

D. How to Rehabilitate Young People with Aphasia

Young people have yet to fully learn how to participate as a member of society. Aphasia can profoundly affect their capacity for academic achievement, their future occupation, their social participation, and their home life, and they tend to withdraw from social situations.

The goal of rehabilitation for children with aphasia is to encourage them to socialize. To make the optimal vocational choice, care should be taken to ensure that they will be able to continue the chosen work. Engaging in any activities that require social participation is recommended. It is desirable that children with aphasia keep in touch with old friends. Speech therapists, family members, and communication partners are able to increase the opportunities for children with aphasia to achieve social engagement. For example, a speech therapist and a homeroom teacher in school could discuss the abilities of a child with aphasia to properly assess what he or she will be able to accomplish as a worker. This will make a positive difference in the affected child's life.

Chapter 89

SUBCORTICAL APHASIA: STILL AN ENIGMA

Lucia Iracema Zanotto de Mendonça*, MD, PhD

Neurology Division of São Paulo University School of Medicine
and São Paulo Catholic University, São Paulo, Brasil

ABSTRACT

The concept that aphasia is caused by subcortical lesions dates back to the 1970s. However, this subject is still controversial, even today. Many researchers believe that the cortex is the neural center for cognitive functions, including language, and aphasic symptoms observed after subcortical lesions may result, in fact, from functional impairment of cortical activity. In contrast, other authors have advocated a specific role of subcortical structures in language. Advancements in our understanding have resulted in a change of focus for this issue. The term subcortical aphasia encompasses cases of aphasia resulting from lesions located below the cortex, which includes lesions to the basal ganglia, thalamus, and white matter. Advancements in our understanding of the fascicles that travel over the white matter and that connect different cortical areas related to language have revealed that white matter lesions can produce various changes in language. Thus, to elucidate the role of subcortical structures in language, unique injuries to the basal ganglia and thalamus must be separated from those that affect the white matter. The aim of this chapter is to present evidence for the specific involvement of the basal ganglia and thalamus in vocal production, speech, and language. Hypophonia, difficulties in speech initiation, disfluency, syntactic deficits and semantic-lexical disorders are specifically discussed. Thalamic and basal ganglia lesions seem to accompany more complex deficits of language. As the entire cortex has access to subcortical structures, even Broca's and Wernicke's areas, through cortico-subcortical loops, subcortical structures are predominantly integration structures and thus can participate in different aspects of communicative function. The participation of fronto-subcortical circuits and the integration with the posterior cerebral areas has been proposed. Subcortical structures possibly play an important evolutionary role in language acquisition by humans. Basal ganglia and the thalamus may have adapted its own *modus operandi* for speech functions. The cortico-subcortical network and the interrelationship

* Corresponding Author Email: lucia.iracema@terra.com.br (Rua André Dreifus – 264 – São Paulo – Brasil; Area code: 01252-010; Tel: (55) 11 – 3285-6046 and (55) 11 – 9.9931-9713).

between corticality and subcorticality should be considered to fully comprehend the function of language.

The notion that aphasia might be caused by subcortical lesions was formulated a few decades ago. Although ideas about subcortical aphasia have evolved over time, the subject remains controversial. Many researchers believe both that the cortex is the neural center for cognitive functions, including language, and that aphasic symptoms observed after subcortical lesions may result from the functional impairment of cortical activity. In contrast, other authors have argued that subcortical structures play a specific role in language.

Subcortical aphasia was initially understood as aphasia resulting from lesions located below the cortex, including lesions on the basal ganglia, thalamus, and white matter. Advancements in our understanding of the subcortical fascicles that travel over the white matter and connect different cortical areas related to language, which have arisen both from tractography [45] and from intraoperative stimulation of patients with brain tumors [23], have resulted in a change of focus with respect to this issue.

According to several studies, the presentation of subcortical aphasia is characterized by wide variability: in some cases, it is similar to classic cortical aphasia, whereas in others, it is not [42].

This variability might be partially understood if one considers that the language function requires both the participation and the interrelation (and thus, the connection) of multiple brain areas involved in phonological and semantic processing [45]. Other cognitive functions (such as executive functions) also participate in language processing. Subcortical fiber bundles connect the multiple brain areas required for verbal expression and comprehension in the context of human communication. Consequently, damage to one fiber bundle might cause disconnection and thus interfere with the language function in a manner that is not necessarily similar to that resulting from injury to the same cortical area.

As a function of the current state of knowledge and aiming to elucidate the role of subcortical structures in language, unique injuries to the basal ganglia and thalamus must be separated from those that affect the white matter. The aim of this chapter is to present evidence for the specific involvement of the basal ganglia and thalamus in vocal production, speech, and language. Because this matter has not yet been elucidated, this work's objective is to present the knowledge provided by recent studies, emphasizing the evidence that seems to provide the most promising basis for future research.

ANATOMICAL-FUNCTIONAL ASPECTS

The subcortical structures discussed in this chapter are the striatum (composed of the caudate nucleus and the putamen), the globus pallidus and the thalamus.

The entire neocortex is connected to subcortical structures. The relationships between the subcortical structures and the cortex are highly organized, i.e., definite cortical areas project to subcortical targets, which in turn send information back to specific cortical areas ⁴, thus forming a cortico-subcortical circuit.

The striatum receives connections from the cortex and projects to the (internal and external) globus pallidus and the substantia nigra. Through a parallel connection to Luys' body, the globus pallidus projects to the thalamus, which through its connection to the cortex completes the circuit. This structure is known as the classic cortico-striato-pallido-thalamo-cortical loop (Figure 1).

Some of the synapses in the cortico-subcortical loop and parallel connections (substantia nigra and Luys' body) are facilitatory, whereas others are inhibitory.

Stimulation and inhibition also occur in the thalamus. The nucleus reticularis (NR) is a thin sheet of neurons that covers the anterior and lateral aspects of the thalamus. The NR receives projections from all of the cerebral cortices and their associated thalamic nuclei in a topographic manner, but it sends inhibitory output only to the thalamus [72]. The area in the NR that receives inputs from a given cortical area (which in turn receives thalamo-cortical input from a given thalamic nucleus) projects to the same thalamic nucleus. The NR is organized into sectors, including motor, limbic, sensory, visual and auditory subdivisions.

Figure 1. The cortico-striato-pallido-thalamo-cortical loop.

In other words, the signals that originate in the cortex might be reduced or amplified both along the cortico-subcortical loop and in the thalamus. The cortical information might be filtered or released in the cortico-subcortical loop; in either case, it is modified. The signals might also be modified in the thalamus, resulting in changes in the information sent to the cortex. The neurophysiological data thus indicate both that the thalamus is a center of integration and that it regulates the flow of information in the brain. Because the cortico-subcortical connections are highly organized and associated with various modalities/functions, they enable the subcortical set both to mediate communication among distinct cortical areas and to participate in the functions performed by the cortex.

The organization of the cortico-subcortical relationships might be exemplified by the case of the connections between the thalamus's medial geniculate body (MGB), which is a part of the auditory pathway, and the auditory cortex [44]. The area of the MGM that receives tonotopic inputs is connected to the primary auditory cortex, which is essentially associated with the reception of sound stimuli. In turn, the area of the MGM that receives non-tonotopic

inputs is connected to secondary auditory cortical areas in which the acoustic stimuli are analyzed. Thus, the cortico-subcortical circuits could drive not only the primary cortex but also higher-order cortices.

The thalamus also includes other nuclei (Figure 2). The centromedian nucleus (CM) is an intralaminar nucleus. It is considered an extension of the brainstem reticular formation, the function of which is to activate the cortex. The thalamic nuclei that are the most involved in language disorders include the ventral anterior (VA), the ventral lateral (VL), the medial dorsal (MD) and the pulvinar (PU).

CM = centromedian nucleus; LP = lateral posterior nucleus; MD = medial dorsal nucleus; NR = nucleus reticularis; PU = pulvinar; VA = ventral anterior nucleus; VL = ventral lateral nucleus.

Figure 2. Thalamic nuclei.

Subcortical Connections of the Frontal Lobe⁴

The frontal-subcortical connections are robust and involve the cortico-striato-pallido-thalamo-cortical loop [8]. The motor and premotor cortices project to the putamen, and the premotor cortex and prefrontal cortices send information to the caudate nucleus.

The motor circuit is the frontal-subcortical circuit that encompasses the projections of the motor and premotor cortices and is related to the motor aspects of speech.

The VL nucleus of the thalamus has been associated with motor control, including speech, because it receives projections from the putamen and information from the cerebellum. Nevertheless, from the functional perspective, the VL nucleus may be subdivided into anterior, middle and posterior portions. The middle portion is more specifically related to the motor circuit. The function attributed to the other portions is described later in this chapter.

The anterior cingulum circuit is motivational, i.e., it is involved in the initiation, maintenance and sequencing of behavior, including speech. The circuits of the orbital and dorsolateral pre-frontal areas relate language to the executive functions, which are relevant for communicative behavior. The main thalamic nuclei that participate in these circuits are the

VA, the VL and the MD. Although the main efference of the MD nucleus is the prefrontal cortex, in particular its dorsolateral portion, this nucleus is also connected to the cingulate gyrus, amygdala and temporal cortex [7], which is important for interaction with the emotional context during verbal communication.

Subcortical Connections of the Parietal and Temporal Lobes

The lateral posterior (LP) nucleus of the thalamus is related to the parietal cortex, whereas the pulvinar is related to all of the retro-rolandic areas and to the prefrontal cortex [36]. Together, the LP nucleus and the PU form the lateral posterior-pulvinar complex, which is the largest nucleus in the human thalamus. From the phylogenetic perspective, in humans, the development of this complex paralleled that of the parietal-temporal-occipital association cortex [58].

Subcortical Connections of Broca's and Wernicke's Areas

Recently, connections between the cortical language areas and the basal ganglia and thalamus have been demonstrated.

Direct connections from Broca's area (the pars triangularis and the pars opercularis) to the anterior putamen and to the nucleus VA of the thalamus have been mapped [24].

Strong connectivity of the thalamus, caudate nucleus and putamen/globus pallidus with Broca's and Wernicke's areas has been found. This connectivity is either bilateral and symmetric [10, 69] or lateralized to the left [10, 69].

These studies indicate the existence of a circuit that includes the basal ganglia, thalamus, and cortical language regions. Although the meaning of this circuit remains unknown, its existence is a prerequisite that substantiates its support for language processing [24].

CLINICAL ASPECTS

Overall, subcortical thalamic and non-thalamic (basal ganglia injury) aphasia exhibit the following characteristics:

- 1) Reversibility;
- 2) Speech motor production disorders: dysarthria, initiation difficulties, speed abnormalities and disfluency;
- 3) Repetition is often preserved [19];
- 4) Fluency: aphasia might be either fluent or non-fluent; and
- 5) Comprehension, which tends to be better preserved than expression. When comprehension is affected, faster recovery of comprehension skills is observed [42].

Differences were described in the presentation of aphasia caused by thalamic versus non-thalamic lesions.

Non-thalamic aphasia is characterized by the wider variability in its presentation. The language disorders associated with non-thalamic aphasia often correspond to those associated with classic cortical aphasia [33]. Hypophonia, i.e., reduced vocal volume, is present. Syntactic simplification of sentences is observed. Phonologic paraphasias are more common in non-thalamic than in thalamic lesions [43].

The manifestations of thalamic aphasia are considered more characteristic. The aphasias that result from anterior or posterior thalamic lesions can have striking similarities [20]. Either speech is fluent [57] or its fluency might be reduced [19] in a manner that becomes dependent on stimulation. Mutism occurs in cases with bilateral thalamic lesions. Patients can show nonfluent aphasia soon after stroke, but within a period of a few days, patients are more commonly described as having fluent output [20]. However, decreased fluency in output might continue for many months after injury [19]. Comprehension is less impaired. Comprehension might be significantly affected, especially at the phrase level, either when it includes many items or when its syntax is complex, which suggests involvement of the working memory [20]. Anomia and semantic paraphasia complete the clinical picture. At times, paraphasias are so severe as to deteriorate into jargon [20]. Lexical-semantic disorders are the most striking characteristic of thalamic aphasia [19].

Next, the pathophysiological mechanisms of some of the aforementioned clinical aspects are described and discussed.

REVERSIBILITY

In subcortical lesions, the symptoms of aphasia are of a reversible, often transient nature. The clinical manifestations might change over the course of a few days [20]. Aphasia caused by subcortical lesions tends to be less severe than aphasia caused by cortical injury. Most patients recover to a significant degree within 6 months of the ictus [29].

The prevailing concept among researchers is that the cortex is the neural center of language. Thus, the symptoms of aphasia found in cases with subcortical lesions result from cortical dysfunction. In turn, cortical reorganization allows for the recovery of the impaired function, thus accounting for the benign and transient nature of subcortical aphasias.

As a function of the relevance of the cortical-subcortical loops, mechanisms that involve diaschisis (cortical functional deafferentation) seem to account for the occurrence of cortical dysfunction. Positron emission tomography (PET) and single-photon emission computed tomography (SPECT) scans of subcortical lesions demonstrated hypometabolism/hypoperfusion not only in the affected areas but also in the distant cortex. Some authors have found an association between the degree of cortical hypometabolism and the severity of speech disorders. Improved performance often occurs in parallel to cortical activity's return to its normal level [13].

In an elegant study using perfusion and diffusion magnetic resonance imaging (MRI), Hillis et al. [34] (2002) have demonstrated both that pure subcortical infarctions are associated with cortical hypoperfusion and that the symptoms of aphasia disappear once the cortical blood supply is restored. However, A.E. Hillis's own group admits to having

observed aphasia in some cases of isolated left thalamic infarcts without cortical hypoperfusion [62].

The cause of the potential reversibility of aphasic symptoms in subcortical lesions continues to be debated.

HYPOPHONIA

Hypophonia—i.e., reduced voice intensity—is traditionally considered a characteristic of lesions that affect subcortical structures and/or their pathways. Upon request, the patient might transiently increase his or her voice volume but then reduce it again.

Little is known about the cortical areas involved in human vocalization. A functional MRI (fMRI) shows the primary sensorimotor cortex, supplementary motor area and anterior cingulum to be active [55].

The motor circuit, which is phylogenetically older, likely controls the voice volume, whereas the motivational circuit is likely involved in the initiation and maintenance of vocalization. The anterior cingulum plays an important role in vocalization in an emotional context ⁷. Adjustments likely occur in the transposition of non-human to human vocalization in the course of phylogenesis.

MOTOR SPEECH DISORDERS

Dysarthria, disfluency with perseveration and changes in the rapidity of speech are found in cases that involve subcortical damage.

Dysarthria

The left putamen receives information from the motor and premotor cortices and participates in the articulation process. Stimulation of the left putamen causes anarthria [28]. The VL is the main nucleus of the thalamus associated with the motor loop.

Studies conducted with multilingual individuals, who exhibit a vast articulatory repertoire, confirm the participation of the putamen in the control of articulation. In such individuals, the activation of the left putamen increases when they speak a non-native language, but only if they are not highly proficient in that language [3]. Gray matter density is increased in the left putamen of multilinguals compared to monolinguals [3].

An affected frontal-subcortical motor circuit may cause dysarthria.

Disfluency

Occurrence of disfluency is frequently reported in cases that involve subcortical injury. Neurogenic stuttering has been associated with lesions in almost any brain area. Nevertheless,

in 75% of the cases documented through neuroimaging, the lesions had a subcortical location [47] in either the basal ganglia or the cortico-subcortical circuit.

Stimulation of the middle portion of the left VL nucleus causes either perseveration on the first syllable [54] or stuttering speech [32].

Studies that are more recent suggest that the subcortical networks related to motor speech extend beyond the VL nucleus. Stuttering or syllable perseveration has been documented after CM thalamic stimulation [5], after stimulation of the internal globus pallidus [52], after combined cerebellar and thalamic lesions [64] and after stimulation of the left caudate nucleus [28]. Therefore, several thalamic nuclei, the basal ganglia and cerebellum are involved in the speech motor function.

The underlying mechanisms of disfluency in subcortical lesions remain unclear. A possible explanation for this phenomenon is that the basal ganglia play a key role in behavioral timing and sequential processing [18]. In language, the temporal sequencing process appears at most linguistic levels, from the sequencing of phonemes to form words to the sequencing of words to form a sentence to the sequencing of sentences within the context of discourse [38]. Altered sequential-processing capacity may explain the occurrence of disfluency and perseveration in the speech of patients with subcortical injury.

The relevance of the left striatum to linguistic sequencing has recently been confirmed. Participants were required either to rearrange materials sequentially based on linguistic or non-linguistic rules or to repeat a previously ordered sequence as a control task. fMRI data revealed a strongly active left-lateralized corticostriatal network that encompassed the striatum, dorsolateral and ventrolateral prefrontal cortex and presupplementary motor area while the participants were sequencing materials using linguistic versus non-linguistic rules.

Non-linguistic sequencing did not recruit this network; instead, its activation foci were both more posterior and more symmetrical. The authors suggest that the anterior striatum has extended its original sequencing role to subserve the function of linguistic sequencing in a domain-specific manner [12].

SYNTACTIC ASPECTS

Significant activation of the left caudate nucleus [50] and left putamen [25, 26] occurs during syntactic processing tasks. Although lesions in the thalamus cause difficulty both in sentence comprehension and in the use of complex syntax for verbal production [22], this difficulty may be caused by the participation of executive functioning and/or working memory, as discussed below. Syntax does not seem to require the support of thalamic processing [20].

Syntactic aspects have been relatively less studied in cases that involve subcortical lesions, particularly cases caused by vascular problems. Huntington's disease (HD) is considered a good model for the study of the participation of the basal ganglia in cognitive functions because the neuropathology at the pre-HD stage appears largely restricted to the caudate nucleus and related structures. It has been reported that Huntington's chorea is related to particular difficulties with increased grammatical complexity [35].

The findings of studies of HD patients have implicated the neostriatum in rule-governed (grammatical) aspects of language that involve both syntax and morphology [53, 65].

Teichman et al. [66] (2008) have applied three rule/lexicon tasks drawn from word morphology, syntax and a non-linguistic domain (namely, arithmetic) in early-stage HD patients. Using PET scanning, those authors have concluded that the left striatum encompasses linguistic and arithmetic circuits. In particular, the ventral area may be dedicated to rule computations.

The grammatical difficulties exhibited by patients with HD do not seem to be caused by an alteration of the working memory. The striatum seems to play a genuine role in syntactic processing that cannot be reduced to its involvement in working memory [60].

A functional cortical-subcortical syntax pathway that links Broca's area (BA45) and the left caudate head and that is associated with syntactic complexity has recently been described [67]. Those authors emphasize the functional relevance of the frontostriatal circuits and the integration of the striatum into this cortex-centered syntax network.

SEMANTIC ASPECTS: FRONTAL-SUBCORTICAL CONNECTIONS

Specific Cortical Activation and Focused Attention

The role of the intralaminar thalamic nuclei, such as the CM nucleus, in the diffuse activation of the cortex is very well known. Nevertheless, there is some evidence that the thalamus may regulate the cortical alertness and activation for a given specific function [51].

Stimulation of the left CM nucleus induces faster, more accurate responses to naming and language-comprehension tests [9]. Stimulation of the anterior portion of the VL nucleus increases speech rapidity and reduces response latency on visual naming tests [32]. Occurrence of tachylalia (increased speech speed) has been described in cases with subcortical injury.

The aforementioned data point to the participation of the activating system. By increasing the excitability of the cortical area to which it projects, this system may promote selective activation of the cortical areas needed for an ongoing function/activity. Multiple cortical areas that participate in the function in question may therefore be activated.

Nadeau and Crosson [51] (1997) have suggested the term “selective engagement” to refer to this process of temporarily engaging the topographically disparate regions of the cortex that are necessary to perform a task. Considering the proposed role of the frontal cortex in this process, the authors considered selective engagement as a form of guided attention.

Several thalamic nuclei have been described as being components of the “specific alerting system” [32], including the anterior portions of the VL, the VA, the CM, the PU and the NR nuclei.

Selective engagement appears to be accompanied by gamma rhythms (20-80 Hz) in both the cortical and the thalamic structures. Macdonald et al. [48] (1998) have shown that stimulation of an NR sector in rats induced gamma-frequency oscillations in the cortical areas associated with that region, which suggests that the NR plays a role in selective engagement. However, other thalamic nuclei might also induce rhythmic cortical activity. The possible role of the pulvinar is discussed below.

The cortico-subcortical loop is perhaps a component of the specific activating system. One study that has applied PET combined with a dopaminergic marker has found a correlation between the speed of phonological processing and left putamen activity [68].

The subcortical structures, particularly the thalamus, may optimize the allocation of focused attention for linguistic processing [49].

The hypothesis that subcortical structures participate in selective attentional processes indicates frontal-cortical connections.

Lexical Selection

Word-finding deficits are frequently found in cases that involve subcortical damage.

Stimulation of the posterior portion of the left VL nucleus and the lateral posterior-pulvinar complex causes anomia [54].

Naming is a complex task that demands the participation of several cognitive processes. In figure naming, visual recognition leads to a semantic representation of the object. The concept is then associated with an appropriate lexicon (word), which is selected among various similar options within the category to which it belongs. Once the lexicon has been selected, the individual must access the phonological representation of the word in question. These steps are interrelated and involve several brain areas.

The left prefrontal cortex is important for the lexical-semantic search and selection mechanisms. Individuals search for and retrieve (access) the lexicon in the semantic memory and select the appropriate option among many competing alternatives, which are then discarded.

Verbal fluency tests reflect this lexical search and selection. Several word generation tasks, such as verb generation [56], generating members of a semantic category and rhyme production [21], are related to the activation of the pre-supplementary motor area, cingulum, dorsal caudate, nucleus of the thalamus VA, inferior frontal gyrus and middle frontal gyrus of the dominant hemisphere. It has been found that the caudate enhances neural activity related to correct choices and suppresses activity related to incorrect choices [15, 16].

Studies of bilingualism have confirmed the relevance of the subcortical structures in the mechanisms for attention and lexical selection. Bilingual individuals need to recruit attention and selection mechanisms to control competition between their two languages. The basal ganglia play a key role in behavioral switching processing [18]. In bilingual aphasic individuals, words from both languages may appear in their verbal expression as a function of the damage to the frontal-subcortical loop [1]. In bilingual individuals, there is now evidence that the head of the left caudate, the pre-supplementary motor area and the cingulum are involved in selecting the less-proficient language when language switching [2, 27].

Therefore, the available studies indicate that the caudate nucleus and the thalamus might contribute to the process of lexical selection that occurs in the frontal cortex. Naming errors and semantic paraphasia may be the result of damage to these structures.

The frontal-subcortical circuits are becoming increasingly relevant in the study of subcortical aphasia. Subcortical lesions seem to be attended by more executive, complex language deficits [11]. In fact, some studies have noted the participation of subcortical structures in tasks that depend on the executive function, such as the elaboration of discourse and the interpretation of ambiguous or figurative passages [14, 17, 37]. Difficulties in

comprehending sentences that are long and that have complex grammar may be related to the working memory [20].

SEMANTIC INTEGRATION

Raymer et al. [59] (1997) have developed a test battery to distinguish among deficits at the purely lexical level, deficits at the purely semantic level, and deficits at the lexical-semantic interface. Those authors have applied the battery to patients with left thalamic lesions, concluding that the problem was located at the lexical-semantic interface. They have hypothesized the loss of the frontal-thalamic system's ability to selectively access the correct word.

However, another explanation is based on an inability to bind the semantic attributes that represent a concept to their corresponding lexical representation, which also results in naming errors. This hypothesis was investigated by Kraut M. A., Hart J. and colleagues [31].

Those authors have constructed a task that probes object retrieval from the integration of two features of the object. For example, "desert" and "humps" can be combined to make "camel."

fMRI has shown that successful retrievals are attended by activation of the pre-supplementary motor area, the caudate nuclei, the thalamic nuclei DM and pulvinar, and ventral temporo-occipital lobes [6, 39, 40, 41]. When object attributes were presented as word pairs, thalamic activity was limited to the left side [41]. When object features were presented in a word-picture pair, thalamic activity was bilateral [40]. Activity in the MD nucleus appeared to precede activity in the PU [39]. Those authors have hypothesized both that the earlier activity in the MD nucleus (with predominantly frontal cortex connections) was involved in a semantic search for a match and that later PU activity was involved in binding the features together in the process of object recognition.

The semantic system is widely distributed in the cortex [30]. The notion of an object derives from its visual image, the sound it produces, the motion it performs, its odor and taste and other attributes, in addition to the word that designates it. Different anterior and posterior cortical areas process the various characteristics of an object and are bound together to achieve its semantic representation.

Several lines of research have demonstrated that the PU synchronizes the neural activity of related cortical regions [31]. Slotnick et al. [63] (2002) have recorded thalamic and cortical activity during a single task of naming a target based on two attributes, detecting an increase in gamma activity at thalamic and cortical locations. Cortical and thalamic responses were phase locked, suggesting that they were related.

The PU nucleus is connected not only to the parietal, temporal and occipital cortices but also to the prefrontal cortex. The pulvinar is ideally positioned to achieve the functional integration of geographically separate but semantically related areas [31, 32, 70], thus uniting various elements to achieve the semantic representation of an object.

That hypothesis does not exclude either the lexical search and selection mechanisms or the role of the frontal-subcortical connections. However, it includes a mechanism of integration between the anterior and posterior areas for the purpose of semantic representation. This model agrees with the findings reported by Raymer et al. [59] (1997),

which indicates that thalamic lesions are associated with a deficit at the lexical-semantic interface. In addition, this hypothesis accounts for the clinical manifestations of aphasia due to thalamic injury, in which the main alteration has a lexical semantic nature and is characterized by anomia and semantic paraphasia.

The participation of the basal ganglia in that model cannot be ruled out, although according to some authors [70], they do not play a role. Lexical-semantic difficulties are found in patients subjected to pallidotomy [71]. Some studies suggest that the striatum is involved in the stage of language processing during which the syntactic-semantic-contextual set is analyzed, i.e., when the appropriate response is selected according to the given context [46]. This late-stage integration takes place after the first lexical access and reflects processing at the sentence level in a given context, i.e., when semantic representation is allied both to the communicative situation and to the grammatical structure.

Based on the current state of knowledge, we can affirm that there is some evidence that the subcortical structures participate in the lexical-semantic mechanisms in harmony with the cortex.

FINAL CONSIDERATIONS

Despite the advances in research and neurophysiological and neuroimaging techniques, we still lack an understanding of the role played by basal ganglia and the thalamus in language. More specifically, the role of the striatum remains controversial.

Clinical practice and research studies indicate that the aforementioned structures participate not only in vocalization and the motor aspects of speech but also in syntactic and lexical-semantic processing.

The primary controversy is between researchers who believe that the symptoms of aphasia associated with subcortical lesions are actually caused by cortical dysfunction and researchers who believe that subcortical structures play a specific role in both language and speech.

Nevertheless, instead of independence, it seems more reasonable to posit an interrelationship between the cortex and subcortical structures. The basal ganglia and the thalamus participate in mechanisms involved in activating and regulating the cortical processing of language and speech.

Any view of the role played by the subcortical structures in cognitive functions should consider the evolution of the nervous system, which occurred as a hierarchical process, compared to the evolution of the most recent structures, whose functions developed over the functions of the oldest structure. In human ontogenesis, the brain maturation process results in the increasing relevance, during adolescence, of cortical regions in commanding the global network, whereas the caudate, cerebellum, thalamus, fusiform and parahippocampal gyri lose their relevance [61]. An older area might adjust to a newer function, not by specifically participating in it but by using its own *modus operandi* to support it. For example, the hesitancy, perseveration in the first syllable and disfluency that manifest in the speech of patients with subcortical lesions may be part of the general problem of initiating and sequencing any movement [8].

Therefore, it is possible that the basal ganglia and the thalamus do not have a specifically linguistic function. However, in the course of evolution they may have adapted a canonical circuitry for speech functions [8].

This subject should instigate further research. Subcortical structures might have played an important evolutionary role in humans' language acquisition. To fully comprehend the function of language, both the cortico-subcortical network and the interrelationship between corticality and subcorticality should be considered.

Chapter 90

APHASIA MANAGEMENT PRACTICE: CARE AND SUPPORT – A MUTUAL CONCERN AND A SHARED RESPONSIBILITY

Maria Nyström

Borås University, School of Health Sciences, Borås, Sweden

ABSTRACT

This chapter describes consequences from aphasia from the perspective of those affected and their close relatives. Nine persons with lived experiences of aphasia contribute to data by means of interviews, published books and diaries, and seventeen close relatives narrated about their situation as informal caregivers. All that information was interpreted in three parts in accordance with a lifeworld hermeneutic approach. The first, which dealt with existential consequences of aphasia, indicated that the intentional, non-verbal act when something is recognized *as* something is *not* affected by aphasia. Aphasia merely affects the world of symbols, which is necessary for interaction with others. It is therefore connected with feelings of alienation, inferiority and shame in social settings. The second part, which dealt with the issue of professional aphasia care, suggests that adequate care from the affected person's point of view presupposes a secure base and a caregiver who recognizes and trusts the patient's ability to think and communicate albeit not always verbally. In the third part the investigation is directed to close relative's situation. It is suggested that a life together with an aphasic person means being used as a bridge between the aphasic person and the surrounding world. This leaves close relatives with a lonely burden of responsibility. Finally a synthesizing analyse suggests that aphasia management practice includes care and support as a mutual concern and a shared responsibility for professional carers, close relatives and community service. The principles for that are outlined under seven main heads.

INTRODUCTION

Many models for recovery from aphasia processes do not take into account that remaining speech impairments lead to difficulties in interacting with friends and relatives,

which in turn, can delay recovery. This chapter on aphasia management practice therefore concentrates on interpersonal relations as a secure base for further rehabilitation.

Aphasia victims meet professional carers from the on-set of their illness. Yet in a literature review Tacke (1999) found no research investigating the carer's significance for the results of the aphasia treatment. On the contrary the review shows that carers working in general hospitals rarely centred their attention on the individual needs of the aphasic patient, with the result that there is little interaction between carers and patients during the hospital stay.

However, interest in caring science research has increased during the 21st century, and it has been found that professional carers can provide support that enhances the patient's self-esteem and help them to gain a positive but realistic view of the situation. Adequate caring might even encourage progress towards rehabilitation, and turn a blocked situation into a secure one. Andersson and Fridlund (2002) found that interactions with professionals were adequate when they balanced and compensated for disabilities. Sundin and Janson (2003) observed patient-carer interactions during morning care, and they interviewed excellent carers, who were recommended for the study by colleagues. Those professional carers neither reflected nor talked much during caring; instead they used their hands to communicate through touching. The carers thought that talking disturbed the ability of severely aphasic patients' to concentrate.

Caring measures also need to take existential issues that follow on from aphasia into account. That is particularly important preventing the development of post-stroke depression. Depression is a common experience related to coping with post-stroke effects and has a negative impact on rehabilitation (Robinson, 2002). Depressed persons with aphasia often suffer from reduced self-esteem, which may change their self-image. Depression may further affect the motivation needed to improve functional independence, as failure to participate in the community due to impaired verbal ability often results in feelings of loneliness and isolation.

That the effectiveness of conventional therapies has not been conclusively proven (c.f. Berthier, 2005) has led to attempts to integrate knowledge from several therapeutic domains in efforts to introduce other strategies. Cunningham (1998) suggested a counselling approach for patients with severe aphasia, in order to facilitate adaptation to the situation. Van der Gaag et al. (2005) proposed that therapeutic approaches should include family members in order to improve quality of life and communication, as most caregiving is provided by close relatives, at least in the long run.

Research into informal caregiving also emphasizes the importance of non-professional careproviders (Lau and McKenna, 2001). Yet little research is directed to close relatives' problems in an abruptly changed life situation (c.f. Sawatzky and Fowler-Kerry, 2003; Blake, Lincoln and Clark, 2003; Tooth et al. 2005). The same is true for close relatives' educational needs (c.f. O'Connell and Baker, 2003).

According to Bäckström and Sundin (2007) close relatives of stroke survivors often sacrifice themselves and disregard their own needs. Wallengren, Friberg and Segesten (2008) describe such experiences as being "shadows", partly because they are invisible to professional caregivers who focus entirely on the patients and frequently forget their families.

The ability and willingness of close relatives to understand and respond to the aphasic person seems nevertheless to be of vital importance. This is in clear contrast to the amount of attention that has been paid to specific problems from the perspective of informal caregivers.

The starting point for the study that now follows is the assumption that we need knowledge about the consequences of aphasia as an existential challenge in order to provide adequate care and support, which in turn can serve as a firm base for further rehabilitation. The first part describes the experience of suffering stroke and aphasia and the struggle to regain the ability to communicate. The second part describes the conditions needed for properly functioning professional aphasia care, seen from aphasic persons' viewpoint. The third part concerns those closely related to an aphasic person, and their need for support from community service.¹ Finally the three parts are compared and synthesized in order to reach a further understanding on how to provide a firm and solid caring base for a person with aphasia, which can serve as a foundation for further rehabilitation.

STUDY DESIGN - A LIFEWORLD HERMENEUTIC APPROACH

The study has a lifeworld hermeneutic design. Lifeworld research emphasizes individuals as living wholes and focuses on the world as it is experienced prior to the formulating of any hypothesis to explain it (Dahlberg, Dahlberg and Nyström, 2008). It does not look at objects and events as such, but at the way in which they are perceived and experienced as phenomena. Lifeworld research basically draws on the works of the philosophers Edmund Husserl (1970) and Hans-George Gadamer (1997).

The interpretative analysis was inspired by Paul Ricoeur (1976). It was through the dialectic of understanding or explanation that Ricoeur developed his interpretation theory, in which understanding and explanation overlap and cross each other. The range of propositions and meanings in the set of data, which is described below, has thus been unfolded in the phases of explanation.

Understanding emerges from the chain of partial meanings moving toward a whole in an act of synthesis, and it relies on the meaningfulness of expressions such as vocal and written signs. This is in accordance with Ricoeur who suggested that understanding, explanation, and interpretation are mutual forms of the concept of understanding that rely on the same sphere of meaning.

In approaching the issues involved in suffering from aphasia, professional aphasia care and being closely related to an aphasic person, interpretations necessarily involve several attempts to explain meanings in the data. For this reason, theories from existential philosophy and psychodynamics are sometimes used as analytical tools. When that is the case the theoretic tool is briefly mentioned in the findings.

Four women and five men, aged 45-72 at the time of data collection, participated in the first two parts of the study. The data comprise transcribed interviews, autobiographies and excerpts from diaries. Data were collected in Sweden, from nine Swedish-speaking informants, who made their contributions to the data set on 16 different occasions. They were purposefully selected from among members of two branches of the Swedish National Fellowship for Aphasia, in order to obtain variation in age, gender, type of aphasia and timelapse since occurrence of the cerebral lesion. Type of aphasia was reported by the informants themselves or their spouses.

¹ The three parts were initially interpreted separately and have been published as three different papers (Nyström 2006; 2009; 2011).

During the interviews it was necessary to communicate in a way that facilitated understanding. Some interviewees could speak adequately, while others still exhibited the symptoms of expressive and/or impulsive aphasia. One important criterion, which limited the number of potential interviewees, was the need to communicate relatively well, orally and/or in writing. In this study communication includes both explicit and implicit meanings that are expressed and interpreted in social intercourse. The interviewees had thus either recovered or learned how to carry on a conversation in spite of the difficulties of speaking or understanding words.

The interviews followed the principles of the life-world approach mentioned above. The interviewees were invited to reflect as openly and deeply as possible on their experiences of aphasia, their struggle to regain the ability to communicate, and their experiences of aphasia care. These interviews were audio-taped and transcribed verbatim.

When more information was required in order to establish the relevance of a tentative interpretation, some informants were contacted again for follow-up interviews. In these interviews the questions were more specific and aimed at obtaining information that could further illuminate the relevance of tentative interpretations (see validity criteria below). The follow-up interviews were not audio-taped but notes were made.

Three interviewees supplemented their interviews with written material that further illuminated their statements. These included diaries or written advice from the interviewees to others with aphasia. Two autobiographies that described experiences of aphasia (Tropp-Erblad, 2002/1882; Dahlin, 1997) were also used as data, but were complemented with interviews. Time lapse since the occurrence of the brain lesion varied from 1-23 years.

The close relatives, 11 women and 6 men, who were interviewed for the third part of the study were purposefully chosen through the aphasia associations. As it was presumed there would be variations in community service they were selected from three different Swedish municipalities, a big city, a smaller town and a rural municipality.

There were 10 spouses, 6 adult children and one parent of aphasic persons. These interviews also followed the principles of an open life-world approach, and all began with a question about what it is like to be closely related to a person with aphasia. The interviewees were encouraged to describe their experiences and their actual life situation as deeply as possible. Pliable probing questions were asked in order to get them to reflect on matters that were not at first described.

INTERPRETATIVE ANALYSIS

Within the three texts statements were compared and put together according to similarities so that further meanings could be abstracted from the data. Tentative interpretations emerged, each illuminating one aspect of the complexity that characterized personal experiences of aphasia, professional care and the situation as close relative. The relevance of the tentative interpretations was evaluated using the following validity criteria:

- The source of an interpretation should only be an actual piece of the data. If theoretical support is used, it is merely as a tool to suggest explanations for a certain item of information. Thus no theory must guide the whole interpretative process.

- No other interpretations should be found that better (more meaningfully) explain the same data.
- There must be no contradictions between an interpretation and the data.
- When more information is required in order to establish the relevance of a tentative interpretation, informants must be contacted again for follow-up interviews.

All interpretations that were deemed to be valid were compared with each other in order to arrive at a comprehensive understanding for each analytical part of the study. In the final synthesizing analysis all three parts were compared, with the following validity criteria in mind:

- The level of abstraction is connected to the principle of moving from the parts to the whole and vice versa, striving for consistency in the jigsaw puzzle of interpretation.
- The consistency of the picture that emerges must be further strengthened by ensuring that no data of general importance are omitted from the synthesizing analysis.

The First Analysis

Existential Consequences of Aphasia

The following first interpretative analysis is based on data from nine informants with personal experiences of suffering a stroke with aphasia. They are also familiar with the struggle to regain the capacity to communicate. As mentioned above, they contributed to the data in several ways by means of interviews, auto biographies and diaries.

Below six interpretations are presented of that information which covers six different aspects of the research phenomenon; existential consequences of aphasia. A comparison of these different aspects culminates in a comprehensive understanding that illuminates the existential meaning of losing the world of symbols. The quotations are excerpted from the data.

It is Essential to Repress Feelings in Order to Act Rationally during the Acute Phase

Despite the fact that warning signs, such as TIA or venal thrombosis, were common, all the interviewees experienced their aphasia as a bolt from the blue. For some, all verbal communication suddenly ceased; while others could speak fluently but without making any sense. Finding oneself in such a situation was generally perceived as a horrific experience, although in retrospect it was only partly associated with feelings of shock and fear.

When the stroke occurred only one interviewee became unconscious, while the others were confused and unable to act rationally. One of them recalled that she just wanted to take a nap and lie down in the snow beside her car. For another, the first indication of a brain lesion was somewhat unusual; he bid on everything at an auction. Those who were less confused recognized that they must act in order to get help, and afterwards they were surprised by their ability to act rationally. One man, for example, was alone in his weekend cottage when it happened and knew immediately that he was unfit to drive. He understood that he had to walk quite a distance in order to contact his neighbour.

Some concluded that the capacity to repress feelings of shock and fear is due to a biological process associated with their cerebral lesion, while others explained their calmness as a mix of biological and psychological processes.

Your body cannot accept that you cannot speak. You can't understand it emotionally. (Is this, do you think, due to the cerebral lesion?) No, not just the lesion, it is also a psychological process.

Such statements indicate that the calm is experienced as a process of repressing feelings as a result of psychological defence mechanisms, such as isolation and rationalisation. The concept of isolation is used by ego psychologists (Freud, 1966; Blanck and Blanck, 1974) to describe mental processes where feelings are separated from thoughts. Isolation as a personal characteristic can indeed be problematic, but it is also an important resource in moments of threat and panic. The isolation of feelings seems in fact to make it possible to put thoughts aside in order to act in a rational manner. The man who became aware of his aphasia while alone in his weekend cottage knew immediately that he must repress his feelings in order to get help and employed his isolation and rationalisation skills as a conscious strategy, contrary to the theory of psychological defence-mechanisms, as an unconscious phenomenon.

When I recognised that I could neither speak nor write I understood immediately that it was important to remain calm and take one thing at a time, and I repeated that to myself every time I was almost seized by panic.

After arrival at the hospital it was possible to stop repressing feelings. This supports the interpretation that feelings are repressed only when it is essential to act rationally. On the other hand, other interviewees stayed calm for a long time, even after their arrival at the hospital. One woman was unaffected by her severe communication disabilities for a period of two years. It was not until she started to speak again that she became frustrated and angry when she was unable to communicate.

It thus appears impossible to fully explain the calmness in the acute phase of aphasia. Nevertheless, it seems fair to conclude that it is important to be able to repress feelings in an acute situation when it is urgent that decisions are made about how to get help.

Emotional Life Is Intertwined with the Struggle to Regain Language

Some interviewees regained the power of speech within three months, but others still exhibited greater or lesser impediments of language, both oral and written, at the time of the data collection. They spoke slowly and now and then failed to find the right words. Some also found it difficult to understand non-verbal expressions, such as nodding for yes and shaking the head to indicate no.

Others could neither count nor estimate time. One woman could not read or write, while others had difficulties writing. A few interviewees failed to understand some questions during the interview, mostly abstract ones. In such cases, being allowed to read the questions increased their ability to communicate.

As time passed and their ability to communicate improved, the interviewees successively became increasingly frustrated and angry at their failure to express their thoughts and/or understand what other people were saying.

Nowadays I am so angry about not being able to speak properly. It [the ability to speak] can be locked away when something else, such as a headache, is bothering me. It is so infernally hard and arduous to think and speak.

One woman recalled two mute years and described a sense of tranquillity that afterwards became totally inadequate for her. When she was unable to express herself she had a feeling of being on the point of death, where nothing seemed to really matter. Another woman said that her head was emptied of all thoughts during the period of severe aphasia.

It was so odd, as if there was no activity in the brain. It must have been the stroke and the oedema in the brain.

After a period of successful speech training, this woman became anxious and frightened, as she felt pressurised by the idea that if one failed to regain the power of speech within five years one would remain mute forever. Other interviewees also reported that their calmness disappeared when they began to speak again, thus implying that the force driving them to speak increased in line with their anxiety. One interviewee, who had recovered from impressive aphasia, recalled having many words in her head but that they were just a chaotic mess. Initially she was calm, because she was able to understand and believed the physicians' reassurances that she would recover. Feelings of anxiety, fear and anger seemed, however, to increase in line with her successful efforts to regain the use of language.

For one interviewee, the acute phase of aphasia coincided with the death of her son. She could not cry "properly", her body just shook. Furthermore, she could not stand being close to others, not even her own family. When she regained her speech she started to cry and work through the sorrow in her heart and was pleased to have her family by her side.

Is language a precondition for feelings and feelings a precondition for language? If so, it would be impossible to explain sadness, rage and anxiety among infants and animals. It seems more reasonable to assume that increased activity and capacity in the brain trigger feelings of despair, and the struggle to regain the power of speech as well as the ability to communicate. Such experiences are probably best understood as an interwoven process of biological and existential conditions that enable the most significant of human abilities: language. Thus it appears important that the initial calmness disappears in order to make room for a fighting spirit.

It Is Not Necessary to Name the World in Order to Recognize Its Meaning

Some psychologists (cf. Blanck and Blanck, 1974) emphasize verbal language as a precondition for thought, especially those thoughts that are necessary for formal operations. In the present study the interviewees with expressive aphasia were silent, even inside their heads, but were by no means devoid of thoughts. They claimed to have been able to grasp meaning without access to words. One of them described how "words ran out of my head" with amazement and confusion. He found that in spite of the total silence inside his head he could still think, albeit non-verbally.

It is not true that you cannot think without words. I just stood there and analyzed the situation. I was totally calm, incomprehensibly tranquil as a matter of fact, and I discovered another language, a nonverbal language, and it worked!

This interviewee talked about a “meta-language”, a non-verbal and silent language, which, according to him, may be hidden behind the verbal language and therefore inaccessible to a person who can speak. He stated that this “meta-language” is complete in itself and consists of entireties, whole meanings. These meanings are experienced as absolute truth, you do not consider any other options or alternatives as meaning already exists.

All interviewees, despite their different types of aphasia, claimed that they had been aware of everything around them in their waking life, despite the fact that they could not communicate anything about it to other people.

I can't explain exactly how it was. I knew that I could think, and I did think, but I don't recall any words.

One interviewee, who was unconscious after the stroke, found that she was mute when she regained consciousness. When she tried to shake her head for no and nod to indicate yes everything went wrong. Her head was empty; she had no access to any words with which to communicate. After a while she recognized single words from time to time, but no coherent language.

Nevertheless, she claimed that she understood everything that was going on around her. Another interviewee knew immediately that he must act in order to get help. He could neither speak nor write, but he could consider his options and ponder alternatives, so as to obtain assistance. A third individual, who had experience of impressive aphasia, claimed to have been able to understand concrete as well as abstract matters in spite of the chaotic language inside his head.

A few interviewees appeared, however, not to understand all the questions during the interview. One of them said that he had learned to maintain the initiative in a conversation in order to avoid situations that included interpretations of another person's verbal messages. When given time during the interview he proved capable of adequately answering questions that were concrete and complemented by gestures and/or written words. He related that, after four years with impressive aphasia, he had learned how to get a rough understanding.

We may all have experience of word-less and holistic meanings in our dreams, and it seems reasonable to interpret the “meta-language” described by one interviewee and the immediate understanding described by most of the others, as an un-reflected dreamlike recognition that does not require words.

In common with some of the interviewees in this study, we are not always as upset as we might have reason to be during the surrealistic experience of dreaming. When we wake up we can be overwhelmed by feelings, but cannot understand the feelings without reflection. Reflection requires access to words. Interpretation of dreams also presupposes language (Freud, 1968). Similarly some interviewees in this study reflected on their initial dreamlike condition for the first time during the research interview.

Worrying About Being Considered Stupid

Becoming fully aware of the consequences of aphasia appears to be both frightening and humiliating, despite regaining the ability to communicate. One man, who had regained all his communication skills at the time of the data collection, recalled his awareness of the gravity of his condition when a physician talked to him to give him an overall picture of his brain lesion, without saying anything about rehabilitation.

It was a shock! The physician pointed to the wall and asked me what it was. The words were not there, I couldn't name anything. Nothing was there!

Another interviewee, who immediately understood his disastrous situation, described in his diary feelings of rage, humiliation and despair, when he realized after some time that his communication impairment would remain, even when the physical consequences of the stroke had more or less abated.

To just sit there mute and stupid, with one's head full of more or less brilliant comments, not being able to make use of them, it is trying, dreadfully trying, and it makes me very angry. I feel totally worthless, like a parcel labelled: "worthless sample".

Several interviewees were in the habit of always using bank notes when they went shopping, in order to avoid the humiliation of failing to hand over the right coins to the salesperson. A communication impediment, or worse, total muteness, was thus experienced as a much more devastating individual catastrophe than any physical handicap. The interviewees described feelings of being locked inside their bodies. They lost their sense of dignity because they were unable to communicate adequately. Verbal language was experienced as a prerequisite for participating in society, and without language they thought that they were considered stupid. The interviewees' self-esteem and sense of dignity were thus threatened by their own interpretations of other people's assessments of their capacity to think and talk properly.

When I lost my speech I lost my sense of security. As I had no words, I couldn't give expression to nuances. When I could not speak I appeared to be a person who could not think in shades of meaning. It was impossible for me to change that, I simply had to put up with other people's way of looking at me.

Existential Loneliness Causes Feelings of Alienation

Most interviewees also claimed that the healthcare system abandoned them, because no professional caregiver supported them in their early efforts to regain the power of speech. Some of them started to practise words at night in the hospital, soon after the onset of their condition, in spite of recommendations to rest and take it easy. A librarian, as opposed to a care-provider, understood one man's mute plea for something to read, after which he started to recall words. In another case, it was the patient's 12-year-old grandson who wrote words on flash cards, to be used for communicating care needs. The absence of professional support in the interviewees' struggle to regain speech gave rise to feelings of loneliness, but even more devastating were the serious consequences for their private interpersonal relations.

If everything previously well-known appears strange, and communication with those around you is cut off, then the soul is incarcerated in an impenetrable prison, it must be the loneliest soul in the world.

A previously unknown feeling of loneliness, which increases and extends to all domains of everyday life, can thus follow the single-handed struggle to regain the ability to communicate.

Feelings of being alone, imprisoned in the body, appear to create a distance to other people. Some of the interviewees no longer knew who they were, because of their inability to communicate adequately. Their identity seemed to vanish and they considered themselves merely as handicapped people. Not knowing who you are and being unable to maintain your self-esteem makes it easy to distrust the good intentions of others.

When B called he said that my speech was much better than last time he talked to me. But last time he said that I spoke just as well as before the stroke.

Existential loneliness seems to increase when other people ignore or make light of the communication impairments. In the most harrowing moments there are feelings of alienation that include both internal life and the surrounding world. One woman, who used to enjoy her own company when thinking and talking to herself, found that she was not the same person inside when she suffered from impressive aphasia. It made her feel completely alone. In the following statement she describes her feelings of alienation after being unsuccessful at an evening course in English.

The last bus was very crowded. I looked at the people. It was like a Brecht play, as if they were wearing masks. I could not see the faces behind the masks, and their eyes were like empty hollows. I got off the bus and started to walk home. When I arrived home my husband looked at me. He was also wearing a mask!

Strategies for Handling Communication Problems Help to Create Some Distance to the Situation

Many statements could be interpreted as strategies for regaining control over a life situation, despite an impaired ability to communicate. As described above, the strategy aimed at regaining control could start with an immediate and single-handed fight to learn to speak again with no help from professional caregivers, who were considered negligent in terms of their responsibility to assist patients in this struggle.

For others, who continued to suffer from the effects of impressive aphasia, it remained difficult to interpret messages from other people. One strategy that could reduce the instances of humiliation was to control any conversation by choosing the topic, which increased the chances of guessing the meaning of the talk. This strategy, however, was not always successful because of the risk of being excluded from the conversation if one guessed incorrectly. Under such circumstances, giving up could be the easiest way out. A more successful strategy was to ask other people to speak slowly, in order to increase the time available for understanding a verbal message. This may be a similar strategy to the one previously mentioned, i.e., avoiding paying with small change.

Other activities that could be interpreted as strategies for increasing control, especially among those who had been successfully rehabilitated, were commitment to other persons with aphasia, either professionally or in non-profit making organisations. Yet another was not to be afraid to make a fool of oneself.

Friends who failed to recognize them as the same person as before the stroke were not considered real friends. Another way to control the situation was to maintain one's self-esteem and dignity with the help of humour and self-irony. Using humour in such a way may serve as an internal triumph in a life situation that might otherwise be hard to manage.

Sometimes I made fun of myself just to make things easier. But I was deeply concerned and frightened.

A common denominator among the different strategies was that they created a distance between oneself and one's problems and motivated the interviewees to undertake various measures. Involvement in something other than problems, also appeared to increase well-being, *for example* taking an interest in the resources available for rehabilitation and policies for prioritising healthcare problems.

To Lose the World of Symbols - Comprehensive Understanding

When the nine persons who described their experiences of aphasia fell ill they were unconscious, confused, or wide-awake and recording what was happening. In spite of initial shock and fear, the following period of silence or unconnected, inadequate words in the head was like a dreamlike state characterized by a surrealistic sense of total calm in the eye of a storm. The external world was experienced as an unconditional entity that could be grasped without being able to talk, and sometimes not even understand, what others were saying. The phenomenological theory of intentionality may help in understanding such a non-verbal, pre-reflective grasp of reality. In employing the concept of "intentionality", Husserl had no doubt about the inherent power of what he called the "natural attitude", i.e., "the everyday immersion in one's existence and experience, in which we take for granted that the world is as we perceive it, and that others experience the world as we do"(Husserl, 1970 in Dahlberg et al. 2008). In the act of intentionality we do not critically reflect, we are merely in the everyday world in which we live.

When the interviewees in this study were stricken with aphasia, they appeared to lose the ability to move from intentional consciousness to reflection. The world around them was taken for granted in the same way as the air they breathed. They obviously did not find it necessary to analyse their experiences, but appeared to remain in intentionality during the time that they had no access to words.

Is it possible to intentionally recognize reality without words? According to Merleau-Ponty (1989), one of Husserl's followers, such a conclusion seems eminently reasonable. Words are not a precondition for thought. On the contrary, thought is a precondition for language.

It [the word] is not without meaning, since behind it there is a categorical operation, but this meaning is something which it does not have, does not possess, since it is thought which has a meaning, the word remaining an empty container. It is merely a phenomenon of articulation, of sound, or the consciousness of such phenomenon, but in any case language is but an external accompaniment of thought (Merleau-Ponty, 1989 p.177).

A further aspect of intentionality is the ability to think in entirety, without words, immediately after being struck by aphasia. Most of the interviewees not only grasped and recognised their reality, but were later surprised at their own calmness as well as their ability to cope with the acute situation. Even those with strong elements of impressive aphasia remembered and were able to describe the acute phase, despite the fact that they were confused when it occurred.

Hence, aphasia reduces neither perception nor the immediate ability to recognise something *as* something, rather the reverse. The act of intentionality appears to be a more powerful experience than ever before when words are lost; it was interpreted as a “meta-language” by one interviewee in the study.

Instead, the devastating consequence of aphasia is its effect on interpersonal life, one’s ability to interact with others. Interaction presupposes symbols and signs that mean something in accordance with convention within a specific cultural context (Charon, 1989). Words, money, signs and many non-verbal expressions of meaning are examples of symbols. In order to communicate we must make use of significant symbols that are accepted as carriers of meaning in our society. Communication also involves the ability to generate a certain meaning in the minds of others, as well as the capacity to understand what others want to say. Impaired symbolization capacity was exemplified in this study by the interviewees’ difficulty in using coins, estimating time and understanding gestures and so on. Most devastating of all was, of course, the loss of those symbols that are important for language. It was not just the written or spoken word itself that appeared to be devoid of meaning but also complementary symbols associated with speech, such as nodding for yes and shaking one’s head to indicate no, recognizing expressions of joy or sadness or whether a voice is raised in anger or happy excitement etc. Due to the impaired symbolization capacity, the most serious existential consequences of aphasia appear to be loneliness, feelings of humiliation, inferiority and alienation when efforts to exchange thoughts, feelings, attitudes and experiences with others turn out to be unsuccessful. The interviewees in this study suffered, or had suffered, from different types of aphasia of varying severity. For some, this condition more or less affected all domains of their ability to use and interpret symbols.

The emotional consequences of the loss of one’s world of symbols seemed to increase the existential consequences. This was most obvious in one interviewee who lost her son two weeks after suffering a stroke and was unable to mourn for him until she regained her power of speech. She could not cry when she had no words, as if tears are also a part of our commonly shared system of symbols. She and several other interviewees described their difficulties in relating to others, not because they could not speak, but due to feelings of alienation. One of them even felt that the people she encountered were wearing masks. There was only one feeling which all interviewees experienced at an early stage, namely anger.

Over time with increased, but still inadequate, verbal communication, the initial sense of calm disappeared and feelings of self-contempt, suspicion and insecurity emerged. This stage of aphasia was like being in prison. The dreamlike state, the silent “intentional world” described above, was now past over and the interviewees were fully aware of the consequences of losing access to those symbols that constitute connecting links in society. They began to struggle to regain speech and other skills that are connected with symbolization, because they now realised that this was the only way to reclaim their position in society. Their fight was associated with many threats to their self-esteem, but those who were successful were no longer locked inside their bodies. Even if some communication impairments remained at the time of the data collection, the interviewees with mainly expressive aphasia could leave their prison having gained an understanding of the importance of communication and interpersonal relations. The most significant sign of successful rehabilitation appears to be the capacity to be completely involved in something other than one’s own problems, such as work, caring for one’s family, commitment to others with

aphasia or political involvement in prioritising rehabilitation for patients with aphasia and so on.

To sum up; the existential meaning of reversible aphasia is that communion, interaction, and interpersonal relations become more important than ever before. Strong elements of continuing aphasia are characterized by a life-and-death struggle to use and/or understand words. Individuals thus affected, even several years after their brain lesion, still find themselves excluded when they fail to express their thoughts and/or guess the meaning of a conversation. In their struggle for existence they need much more time than they are given to talk and/or to fit the puzzle of their fragmented impressions together. During such circumstances it is impossible to direct interest beyond oneself in order to be involved in something other than a struggle for language. The existential meaning of continuing severe aphasia is thus characterized by alienation and loneliness, leaving the individual to find a balance between a fight filled with agony and giving up in order to avoid further humiliation.

The Second Analysis

Professional Aphasia Care

It seems fair to assume that the most devastating consequences of aphasia could be successfully reduced if the principles for care are based not only upon carers' professional opinions, but also on aphasic persons' experiences of good professional care. The following second interpretative analysis is therefore based on data from the same nine informants as were used in the previous part, with focus now on their statements concerning aphasia care. They talked about care that was provided by aphasia therapists, physicians, registered nurses, nursing aides and physiotherapists. In the findings below all professionals are designated "carers". Seven interpretations that illuminated different aspects of aphasia care are presented, followed by a comprehensive understanding. The quotations are excerpted from the data.

Preventing Isolation

This interpretation describes trust in the patient's competence to participate in caring, because a patient with aphasia can be isolated in different ways. The serious effects of impressive aphasia can make communication extremely difficult, although complementing spoken language with gestures and written notes facilitates understanding, and invites the patients to enter a caring relation.

It is important that the carer writes some words and points to things while talking.
That makes it easier for me to guess the meaning of what she is saying.

With expressive aphasia it is important to continue to talk, even if the patient is unable to reply.

Talk to us! We do understand!

To prevent isolation it is vital to discover how the patient can best take part in interpersonal interplay. Communication can be facilitated by eliminating disturbances such as noise and reducing the number of persons participating in a conversation. It is most essential

to allow the patient sufficient time to concentrate on finding the right words or guessing the meaning of a verbal message. One interviewee with mainly expressive aphasia said:

When I can't find the right word, the other person can become confused. But given time to close my eyes and search for the right word in my head I can do it.

Another interviewee with mainly impulsive aphasia commented:

It is very hard for me to understand when carers are talking. When I finally find out the meaning of a conversation it has already passed. When people are talking at a normal speed I simply have no chance of following the conversation.

The professional carer's adaptability to the patient's competence and contribution to communication, even if it is non-verbal or very hard to understand, must accord with a unique brain lesion, a unique type of aphasia and, most importantly, a unique person. Carers thus need knowledge and proficiency concerning different types of aphasia in order to understand how to make individual adaptations and help the patient to practice language and break down his/her isolation.

Straightforwardness

This interpretation describes trust in the patient's competence to cope with a situation. The interviewees described how they felt when they were ignored because of their impaired use of language.

She [the nurse's aid] put the newspaper on my bed, but didn't say anything. After my aphasia she never talked to me again, and avoided eye contact. I understood that she was afraid. Therefore I also became scared.

Such feelings increase when patients are treated as if they cannot cope with their situation. Implicit assumptions about inability can alienate the patient from the caring situation. The opposite is also the case. Being met with straightforwardness makes it easier to cope with a sense of being trapped inside one's body. Straightforwardness also implies an invitation to enter into a communion where the patient recognises that the carer can – and really wants to – meet with him/her as an individual.

Professional carers ask me if they should supply the right word when an aphasic patient can't find it. I reply that it depends, because we are not all the same. You simply must ask!

This aspect of caring is especially obvious when a carer appears to be uncomfortable with the caring situation or makes light of the problem by saying, for example "you will soon recover", without knowing anything about the severity of the brain lesion.

Today the physiotherapist said that I talked better than on the previous occasion. But on that occasion she said that I talked well.

If any kind of dishonesty is obvious it is natural to become suspicious. An honest invitation to communicate includes opening up in a direct, straightforward and benevolent manner in an effort to understand the patient. Lack of straightforwardness can be a threat to the patient's self-esteem, and if any kind of dishonesty is recognized it is easy to become suspicious. The reverse is also true. A straightforward approach can reduce anxiety about failing to talk or understand.

Provision for Security

This interpretation describes trust in the patient's competence to feel safe with a carer who really wants to understand, because patients with aphasia can be terrified, even horror-stricken, when they become aware of the consequences of their brain lesion. A secure caring base can alleviate such suffering.

A feeling of security makes it easier for the patient to recognise whether the care is based on genuine interest or a wait-and-see policy. When a patient realises that the carer really wants to know and understand, he/she finds it easier to feel safe. Genuine interest implies that the carer is trying to obtain an overall picture of the patient's communication impairment in order to adapt to it. It does not, however, mean that all patients are emotionally ready to face a sudden, unexpected language defect.

It was a shock! The physician pointed at the wall and asked me what it was. The word wasn't there, I couldn't say anything. Nothing was there!

Thus, adaptability that takes each individual patient's reactions into consideration is of vital importance for a secure caring base. It is important to understand when a patient lacks emotional insight into his/her language impairment.

Patients who are not ready to be confronted with their communication impairment can become afraid if the timing of such confrontation is wrong. This kind of awareness on the part of a carer is illuminated by the following statement:

When I arrived in the hospital a nurse talked to me in a warm and calm way. I felt small and helpless. I appreciated her not giving me any information at that moment. She just talked to me in a motherly way.

Recognition of Caring Needs

This interpretation describes trust in the patient's competence to communicate caring needs, because patients with aphasia are vulnerable, as their ability to initiate a dialogue is extremely limited. Professional aphasia care thus includes sufficient time to identify caring needs that are not expressed verbally. It is most important never to allow the patient to feel excluded, isolated and alienated from the caring situation.

To just sit there mute and stupid, with one's head full of more or less brilliant comments, not being able to make use of them is trying; infernally trying and I became very angry.

If caring includes supporting communication when a patient fails to find the right words or cannot answer at all, the risk of exclusion is reduced. It can also be beneficial to slow down

the conversation, complement it with gestures, and help the patient to concentrate by reducing disturbances such as noise.

Yet, the interviewees in the study recalled carers who conversed with each other over their heads. Such attitudes made them feel excluded and humiliated. One interviewee, with expressive aphasia, emphasised:

We can understand what carers are saying and doing although we cannot always give an answer.

Encouraging Efforts to Practice Language

This interpretation describes trust in the patient's competence to regain lost capacities. The interviewees were angry when they recalled carers who did not support their efforts to communicate. Some carers only recommended rest and taking it easy, leaving them to practise words on their own. A librarian, not a carer, understood one interviewee's silent prayer for something to read, and the textbook she provided helped him to recall words. In another case a patient's twelve-year-old grandson made flash cards with letters and words to be used for communicating caring needs. Aphasia care thus includes language practice during caring activities, as indicated by the following:

One nurse continued to talk to me while she helped me to eat and get dressed. She talked as if she knew that I understood, even though I couldn't answer. That made me feel calm and secure and I knew that she would take good care of me.

A carer who encourages efforts to practise language can increase the patient's motivation to communicate, as well as create trust in the carer's ability to understand caring needs. An invitation to practise language indicates that the carer knows that the patient can understand. Several interviewees were critical of carers who did not take on this responsibility. A further aspect of this failure to take responsibility was that professional carers did not inform the authorities about the need for support from the community services.

Equality

This interpretation describes trust in the patient's competence regarding personal interaction. When patients are confronted with their impairment during conversations with carers they can find themselves in a weak position. Inferiority and lost self-esteem remain for the duration of the aphasia.

The worst was not the handicap itself, but my feeling of being disadvantaged.

When carers do not speak to their patients, or converse with each other over the patients' heads, they relinquish the opportunity to create a working alliance to achieve a shared goal, i.e., communication.

It wasn't nice at all when the nursing aid only told me what to do, but otherwise did not speak to me.

No effort should be spared to create an equal working alliance with the patient. In an autobiography, one interviewee contributed the following example highlighting the importance of equality between carer and patient.

If one talks to a patient on the basis of personal experience one may expose one's own weakness. By so doing the carer raises the patient to her own level. She dares to make the patient equal and at the same time relinquishes some of her power. If she divides her strength the patient's strength increases, because he is no longer the only one who is unsuccessful (Tropp-Erblad 2002 p 35).

Supporting the Maintenance of Identity

This interpretation describes trust in the patient's ability to recognize his or her previous competence, as aphasia can include doubts about who you really are. Such doubts not emanate only from the risk of appearing stupid in the eyes of others, but from a deep anxiety about one's cognitive ability.

When the aphasia therapist showed me pictures of the brain I became aware of the fact that I didn't understand as well as before. She also asked me to put a pen in a box but I didn't understand her instruction. Now I really had a reason to be scared.

Expressive aphasia is characterised by failure to make other people aware of one's capacity to think and understand. It is therefore a relief when a carer makes it clear that he or she knows that the patient can think. It is also easier to maintain a sense of being the same person as before when the carer refers to the patient's previous competence.

I couldn't answer, but I think he should have recognised that I understood such matters.

The significance of being aware of the patient's previous competence is also obvious in the following statement. This interviewee is a former physician with severe expressive aphasia. The neurologist told him what had happened by referring to his medical knowledge.

Then I understood that a part of my brain at the back of my head was more or less gone. It can no longer communicate. Perhaps it is possible for that part of the brain to connect to the undamaged areas. Perhaps an undamaged part that is not yet functional can be activated.

This interviewee had extreme difficulty understanding verbal messages, but was nevertheless able to reflect on his chances of rehabilitation by discussing the situation like a physician. The colleague who helped him to understand referred to his professional identity, which helped him to maintain that part of himself.

Adequate Aphasia Care - Comprehensive Understanding

Patients with aphasia know the meaning of language more fundamentally than they ever did before. They know that with aphasia follows existential shortcomings characterized by the loss of almost everything vivid and important connected with interpersonal relations, leaving

them with lost self-esteem, a weak identity and loneliness. A professional carer must thus know how to handle implicit non-verbal questions about who the patient is, as well as feelings of inferiority, frustration and anger.

Trusting the patient's competence while encountering such existential short comings requires a straightforward equal caring relation, which can alleviate inferiority, loneliness and doubts about oneself.

Such encounters are also characterized by the carer's awareness of the patient's possibilities and wishes for support in their efforts to understand and/or to be understood. Adequate professional aphasia care can create a sense of security and community, maintained identity and integrity when the patient is allowed to guide the carers' efforts to discover the best way to practise language.

The most important issue in professional aphasia care is thus to trust the patient's competence while facing existential issues. Such skills can form a secure base that enhances the patient's self-esteem and helps him or her to gain a positive but realistic view of the situation.

The Third Analytic Step

Being Closely Related to a Persons with Aphasia

The third interpretative analysis which follows, is directed towards those closely related to persons with aphasia.

It is based on interviews with seventeen persons with personal experiences of being a spouse, parent or adult son or daughter of a person with severe communication impairments.

The interviewees were encouraged to describe their experiences and their own life situation. Four interpretations emerged, which resulted in a comprehensive understanding that highlights the meaning of being a bridge between a lonely soul and the surrounding world.

Losing Freedom

For close relatives, especially the spouses, communion and cooperation in one's daily life disappear when life abruptly changes after the onset of aphasia. One woman whose husband suffers from severe expressive aphasia says:

I always have to consider the fact that his aphasia makes it frightfully hard for me to be in contact with him, and that leads to loneliness for both of us.

This woman claims to be disabled herself due to her husband's communication impairment. Moreover, he takes her care for granted and is unable to understand that this imprisons them both. Another aphasic man discussed community services without consulting his wife because he wanted her to "take care of everything". Both these women had to take early retirement in order to look after their husbands. Other spouses describe similar dilemmas:

I have to give up what I want to do for myself, because it is a part of the aphasia that they do not want to do anything by themselves, they want company all the time.

He knows what he wants and what he does not want, but I don't exist as a person anymore. He does not understand if I am tired or in pain. No, no, he says if I try to explain. So I am not allowed to have feelings.

I can't give her any responsibility or trust her to do certain things. The whole responsibility lies on my shoulders, in all matters. I often think about the lonely responsibility that makes my life so constrained.

Living with an aphasic person thus means being taken for granted as an informal caregiver, whether or not you have agreed to it. Moreover, none of the interviewees were ever asked by an employee from the community services if they could handle such a situation.

The worst thing that could ever happen to me is to be caught in the situation of being a next-of-kin caregiver after retirement. Worst of all is the humiliation! No one ever asked if they had the right to destroy my life, and that is a deceit on the part of the municipality."

It is devastating always to be restricted by another person's presence, even if it is your husband. You can indeed love a person, but not in a self-sacrificing way. You must have the right to live your own life! This right must be understood by those who decide about community services.

An adult son of a mother with aphasia emphasized the importance of knowledge. He believes that the lack of interest from the community services and political board is due both to a lack of knowledge and to the low status of all illnesses that mostly affect older people. According to him, one manifestation of such an attitude is that aphasia associations rarely receive financial support from the municipality, even when they ask for small contributions. They do not even respond to easy solutions to problems:

Where I live, in my municipality, many computers are written off every week. It would be easy to load them with programs designed for aphasic people and out them in a meeting place for persons with aphasia. But when I suggested that, they were not interested at all.

Thus, the freedom of close relatives to make choices appears to be lost, especially for those living with the aphasic person. Their lost freedom can be interpreted from two different points of view. The first is the aphasic persons' reduced capacity to understand other people. The second, which greatly contributes to having fewer choices, depends on shortages in the community services. This forces relatives to take on the role of informal caregivers, whether or not they have agreed to it. When the French philosopher Paul Ricoeur (1966) considers the voluntary and the involuntary, he emphasizes that only nature is involuntary. It is indeed impossible to escape the consequences of a brain injury. In this study, the close relatives appear to be well aware of the involuntary nature of aphasia, and they accept it. Yet, it is also obvious that the other aspect of constrained options is voluntary limitations as they are caused by people; here shortfalls in community services.

Choices presuppose the possibility of expressing one's wishes, and a sense of freedom depends on one's possibility to say no. If informal caregivers have that possibility, it seems fair to assume that it would increase their capacity to deal with the difficult and challenging life-situation of being closely related to a person with communication impairments.

Staying

The close relatives in the present study, however, did make one important choice: they stayed. They knew that in similar situations, some people, especially spouses, would not. Some of the interviewees had considered divorce or, in some cases, their workmates had suggested it. Nevertheless, they did not find it a solution as it was impossible for them to leave a loved one, even though a future life together seemed to be filled with problems. The choice to stay is even more obvious to those who are a parent or the adult child of an aphasic person. Yet, irrespective of relationship, they all emphasize that aphasia is the worst possible consequence of a brain injury.

Aphasia is the most devilish of all the impairments due to stroke. I can accept that she is bound to a wheelchair, but the loss of the ability to speak is unbearable. I don't even know how she feels about it herself. Some linguistic capacity often returns after a while, but then changes in character and temper may occur. Bad temper is often directed towards those who are closest. One husband puts it this way:

I seem to fuel her anger merely by opening my mouth. She wants to decide everything. She has changed. She came back from her aphasia, but at the same time she did not. Our relationship has become tenser. I think that we would have become closer if she never had that stroke.

One daughter described her mother as formerly a cheerful person, but after a stroke resulting in aphasia, the mother uses bad language.

My mother always liked to joke. Now she is rough; her words are vulgar and she uses bad language. The first word she said after her stroke was a curse word. I feel bad when I hear her talk like that, and I feel sorry for her because I don't think she means it.

A wife described her despair as her husband is angry with her most of the time:

It would never have happened before, that he was angry and irritated with me. Initially I told him how sad I was when he was angry with me, but now I have learned to stay calm.

In order to understand the complexity of a person's choice to stay, it is important to consider the fact that apart from all the frustration, sadness and the heavy burden of responsibility, close relatives know that the aphasic person is helpless without them. Therefore, they try to keep in mind that an aphasic person's loss of empathy with other people's needs, as well as their bad temper, is caused by the brain injury. Consequently, it seems reasonable to understand their choice to stay as a duty. Irrespective of whether the decision to stay concerns spouses or parents or adult children, their motto seems to be, "for better or worse".

The French philosopher Emmanuel Levinas (1972) recognizes the acceptance of other people's right to be different from ourselves as an ethical issue. Such an attitude creates a distance from oneself and one's own problems and opens up a space for demands from the other. The duty to stay has an ethical component, as fundamental ethics mostly concern

interpersonal relations in general and people close to us in particular. Such ethical assumptions make it possible to put the focus on aphasic person's difficult situation rather than one's own problems. Yet, the close relatives in this study did not talk about duty. They talked about love. Their love conquered all temptations to focus on their own life situation. Love made them reject the idea of another life without the heavy burden of being closely related to a person with communication impairments.

My colleagues did advise me to divorce her. Nevertheless, I thought that this was something that had hit both of us, and I still love her."

Creating a New Relationship

The person who once existed is partly lost because of the brain injury, and this loss is certainly recognised by the close relatives. Their sorrow does not merely concern the loss of verbal language but of the whole person.

My dad was always cheerful and chatty. To lose that contact was hard for me.

I try to get in contact with my father, but it always makes me sad because there is only a part of him left.

The contact between my mother and me really changed after her aphasia.

I cried in despair every day the first year. It was a total catastrophe.

Other interpersonal relations, such as those with friends and workmates, dramatically worsen for the affected person. One important part of the close relatives' sad feelings is watching a beloved person's loneliness.

My wife had many friends before she was ill. Now I believe that they were not real friends, because they never visit her. Nevertheless, I think that she thought that she had a rich social life before her brain injury. Now she doesn't seem to care, but I believe that it remains a disillusionment for her.

The initial period of shock and sorrow gradually changes into an insight into the consequences of aphasia. Gradually the sorrow is worked through, and a new form of relationship emerges. Now it is also possible to see small gleams of light.

When you can reach into his consciousness, it is possible to recognize that he is still a man of intelligence.

With the use of words so limited, the close relatives work hard to find new ways to communicate. Their inventiveness is huge; questions and guesses are supplemented with gestures, pictures, special noises etc. Sometimes it is easier to sing than talk. However, all such techniques take a lot of time.

You have to do twice as much in half the time. And you have to be well structured and predictable all the time.

An adult child can be transformed into a parent of his or her own parent after the onset of aphasia. The easiest way out of such a situation can be to concentrate on the practical things that need to be done.

Searching for a new foundation to the relationship can also include new things, such as buying a puppy or listening to music and singing together.

Spouses of aphasic persons spoke of diminished sexual desire, but this did not necessarily mean that their closeness was lost. The longer time spent on understanding each other could in fact lead to a new form of closeness.

We can sit and hold hands for quite a long time. We cry together and he dries his tears with my hand. So our relationship has changed, but not for the worse.

Some alterations in personality can even lead to changes for the better.

My husband cares much more about me than before the aphasia. He was very outgoing before he became ill, and he always wanted to do things with his friends. Now he is keener on me.”

The initial period of chaos and shock is eventually replaced by one of mourning, followed by a period where it is possible to work through the loss of an earlier relationship and adapt to a new one. Various ways to communicate are tried out and concrete solutions to problems emerge.

The loss turns into a commitment to the person who actually exists, with his or her communication impairments and changes in character. From this follows a new sort of relationship and sometimes a new form of closeness. The creative work of building a new relationship varies, and it fluctuates between despair, exhaustion and acceptance.

Yet, there is something that does not vary. The close relatives search for some remaining essence of the aphasic person’s personality. According to the German philosopher Edmund Husserl’s phenomenological philosophy, an essence is described as a structure that makes a phenomenon into that specific phenomenon. This essence illuminates those essential characteristics without which it would not be that particular phenomenon (Dahlberg et.al, 2008), in this case the spouse, parent or adult child who is affected by aphasia. In the close relatives’ efforts to find a beloved person’s essence, they separate the impairments caused by the brain injury from the characteristics they recognize and recall from the time before the injury. Thus, they search for a genuine personality that still exists. If this essence disappears, the beloved person is gone, but this is not true of any of the cases of this study.

Yes, he is emotionally shallow now, but his genuine feelings for me and the children are still there.

I think that her original personality, with a fighting spirit, was a lot of help to her when she started doing things again after her stroke.

The lovely girl whom I always had is still there. She hugs me when she visits us and when she returns to her nursing home.

I am pleased to notice that his strong will is intact, because that makes his life endurable.

The close relatives hold on to this essence when reaching the aphasic person even though verbal communication appears impossible. Hence, their new relationship is built on perceptions of the essence of the person who was there before the aphasia.

Growing Strong Together with Others

As previously mentioned, two wives in the study were forced to quit their jobs, and many close relatives had no time for hobbies. Some of them conceal their problems by erecting a façade in order to avoid putting more strain on the family, as they reject the idea that hardships bring a family closer together. Moreover, they have found that the well-developed welfare system and community services in Sweden are a myth.

When discharged from hospital, the close relatives wrongly took it for granted that community services included access to a speech therapist. They were not informed about the limitations in community services, especially after the retirement age in Sweden, i.e., 65 years. The only exception is a spouse who was lucky enough to be included in a research project.

My husband participated in research and that included a speech therapist three times a week. The speech therapist also talked to me, and it was fantastic to be supported in my communication with him.

Yet, most close relatives in this study were left alone with their fumbling efforts to find new ways to communicate. No professional caregiver ever taught them how to do this. Moreover, socializing with friends or alone also became something of a luxury.

I feel so good when I have the opportunity to exercise and have coffee and a chat with friends. We discuss books, the theatre, lectures, travels. We all laugh and talk a lot.

My dream is to be alone in my own home without the obligations to wait on someone all the time. Or, imagine getting a whole night's sleep!

Under such circumstances, being included in new forms of fellowship with other people in the same situation can compensate for the loss of earlier networks and shortcomings in the community services. Membership of aphasia associations thus turns out to be important and valuable.

In the aphasia association, I meet people who generously share their experiences; this makes me feel very good. It is easier with people in the same situation.

In the aphasia associations, it is easier to take part in activities together with the aphasic persons.

We enjoy travelling with the aphasia association. Such possibilities are worth a lot. Stimulation is really important, and being able to visit other countries gives a lot. Much of that pleasure remains when we return home. We look at photos together and remember many good things.

It is a relief to find people in the same situations who are able to share their experiences. Such fellowships make it possible to create meaningful activities together with the aphasic person and enjoy moments of relaxation with other close relatives. One important aspect of such encounters is the ability to confirm and receive confirmation in terms of vulnerability as well as an unexpected capacity to deal with problems. Moments to oneself, or with others who are able to understand, make it easier to discover one's own hidden resources.

The British psychoanalyst Donald Winnicott (1971) introduced the idea that moments of active relaxation alone or with others constitute a "potential space" which makes it possible to work through thoughts and feelings. He claims a potential space is an area between the internal life (fantasy) and the external world (reality). In the potential space, we have access to both. This makes it possible to reflect on problems and solve them, initially by imagining possible solutions and then by trying to solve the problem in one's mind. Therefore, having a potential space is an important resource for regaining strength. Fellowship with others in the same situation and the chance to be alone some time appear to increase the possibility of growing stronger than could ever be imagined.

I have got a new insight. I think that everyone has much greater resources than they know. Human beings seem to have a kind of preparedness for dealing with difficulties but you are not aware of that until something happens.

Being Closely Related to a Person with Aphasia - Comprehensive Understanding

The four interpretations above illuminate how aphasia affects the daily life of close relatives. Their life fluctuates between feeling imprisoned, when they understand that they cannot count on the community services, and growing more confident of their ability to handle the situation. The way to better self-confidence is paved with setbacks, feelings of powerlessness and despair, but also glimpses of hope.

The first analysis in this study shows how people with aphasia feel empty in their internal worlds with no access to adequate words for their own brainwork. Aspects of the same phenomenon appear to be reflected in the close relatives in this third analysis as they become tied to an aphasic person and lose the opportunities to do things with other people or by themselves. Leaving the aphasic person alone is not an option, because that would mean leaving him or her empty both in internal and external sense. Therefore, they strive to find new things or new ways of doing old things together. During that process, they create a new form of relationship.

Being closely related to an aphasic person thus seems to comprise existential issues, which in turn raise identity questions such as: Who was I before? Who am I now, when my chances to choose my own way of life are gone? What will I be in the future? Will I always be reduced to an informal caregiver?

One tentative explanation for such an identity crisis is that close relatives seem to take on the part of acting as an extension of the aphasic person's body and mind. According to Maurice Merleau-Ponty (1989), our "lived bodies" can be extended by using *things* that

increase our possibilities to participate in the surrounding world. Some well-known examples from that element of Merleau-Ponty's philosophy are a cane or a pen that are experienced as the prolongation of an arm or hand, or music instruments or cars as extensions of one's body.

Merleau-Ponty also stresses that all forms of illness result in changed access to the world because of one's lost abilities and interruptions to harmonic living. This is certainly true when the most important part of the body, i.e., the brain, is struck by illness. Aphasic people find themselves in a situation where it is necessary to rely on others as extensions of their body and mind. Being closely related to an aphasic person consequently includes a tendency to be used as a *thing*, in the sense that Merleau-Ponty suggests or, to put it more concretely, as a bridge between a lonely soul and the surrounding world.

A common denominator in the four themes described above thus concerns new ways of viewing oneself. The close relatives gain an acceptance of their current life-situation, that is beyond their earlier capacity. They decide to stay and continue to serve and love. In doing so, they also make a knowing which gives them confidence in their self-image as a person who does not desert a loved one.

The Synthesizing Analysis

Aphasia Care and Support- a Mutual Concern and a Shared Responsibility

The first part of this study illuminated how a person with aphasia copes with existential loneliness and feelings of alienation in social settings. The possibilities to be part of the communion appear not only to differ according to the type, severity and reversibility of the aphasia itself but also to other persons' wishes and capacity to interact in spite of obvious obstacles to communication. The second part described how professional carers can be of assistance in the struggle to regain communication skills by trusting the patients' competence. The third part was directed to something often neglected, the close relatives who are informal caregivers. The meaning of that was interpreted as being a bridge between a lonely soul and the surrounding world.

Putting one's feelings into words is a well-known psychotherapeutic basis for achieving awareness of one's motives and choices (cf. Blanck and Blanck, 1974). According to Gadamer (1996), words are "food for thought", and humanity would have been unable to construct cultural traditions without the miracle of language. A further important aspect of language was introduced during the 1930s by George Herbert Mead (1934). According to him, human communication is a consequence of role-taking. In order to communicate, every person must be able to assume the role of the other and address him or her in a language that both understand. In other words, we cannot begin to communicate without making assumptions about the internal operation of the mind of the other. Role-taking thus carries with it enormous social and personal benefits. It allows genuine interaction, and permits cooperation and compromise as well as making possible a depth of interpersonal relations that would otherwise be unattainable. This is also important for our capacity to use and understand symbols and signs in accordance with our cultural tradition.

Thus, aphasic people are certainly vulnerable, as their ability to enter into a dialogue on their own initiative can be extremely limited. Therefore, conversation in line with their communication impairment, is essential for their ability to participate in social life. In this process it is important not to conceive of language as a form of adherence to fixed rules. The

real miracle of language is to be found when the aphasic person discovers the meaning in the words of someone else and is able to express meaning themselves.

Many health care theorists also emphasize the power of interaction between a professional caregiver and patient. According to Peplau (1991), a professional carer must also understand his or her own behaviour in order to help patients to understand how their individual disabilities and impairments affect their situation.

Apart from a few studies within healthcare science, reflections on interpersonal relations in the care of patients with aphasia appear to be quite rare. Coping with the most devastating consequences of aphasia seems nevertheless to be related to interpersonal relations. It thus seems reasonable to suppose that inferiority, self-contempt and suspicion can be successfully reduced by means of positive communication, interaction and a sense of community. Thus, a caregiver's capacity to assist in finding that symbols function for communication is of vital importance for patients with continuing aphasia.

Some of the professional carers referred to by the informants in the second part of this study appear to have been able to create a starting point for acceptance and working through the dreadful experience of losing the world of symbols, by trusting and assisting the patient's competence to deal with such losses. One question, however, remains. How can another person know about individual existential issues if the aphasic person cannot put them into words? There seems to be an urgency in pondering whether language has an existential meaning in itself, or if the meaning of language is best understood by those who have experienced losing it?

According to Martin Heidegger's existential philosophy the breakdown of a tool momentarily highlights its presence (i.e., *Being* in Heidegger's terminology) in the "world" in which it exists (Heidegger 1998). If this is the case even with such a fundamental "tool" as language its full meaning is visible to those affected by aphasia, while it is hidden from everyone who has not had such an experience.

This is, however, a poor consolation to those affected. Frustration, anxiety and anger seem to be important aspects of the struggle to regain the capacity to communicate, as they contribute to the disappearance of the illusory initial calmness, thus making room for a fighting spirit. Even those with continuing aphasia appear to be helped by their frustration, as it serves as a driving force that motivates them to practise speech and written language.

But for those closely related, especially spouses, easily awakened frustration and anger can be experienced as frightening personality changes. When the brain injury also includes impairment of the skill to understand and show an interest in other people the strain on close relatives is further increased.

In the first analyse this was exemplified by the aphasic persons' experience of being empty inside their head. Difficulties in improvising thoughts and indulgence in daydreams made them lonely, not only in social settings but also in an internal sense. That, in turn, could increase their need for another person's constant presence.

The same issue was illuminated from another aspect when close relatives were interviewed. Spouses in particular claimed to be trapped without the chance to do anything for and by themselves. They had turned into extensions of the afflicted person's body and mind.

Yet, such consequences of the brain damage were not the most frustrating part of the close relatives' lost freedom, which was the lack of support from community services. Hence, there are consequences to being closely related to an aphasic person that appear to be

unnecessary; they depend on an insufficient community service. If close relatives' fundamental rights to decide how to manage their own lives are attended to, it will probably enhance their ability to assist a family member with communication impairments. It is therefore important in providing professional help to include issues concerning how to balance their responsibility against the responsibility of professional carers and community service.

It is thus reasonable to conclude that aphasia management practice, in the long run has to be a shared responsibility. Principles for this can be outlined under the following headings:

- The first task is to provide the aphasic person with a secure base, consisting of *both* professional support and informal caregiving of close relatives. The secure base can form the starting point for exploring possibilities for interpersonal communication with help from a trusted companion who continues to talk even when answers are lacking.
- The second task is to encourage the aphasic person to consider how current perceptions and expectations can make room for a fighting spirit. Some require time, while others immediately start searching for a way out of their verbal prison. For the first group the spirit can be even more paralysed than the body, but for all it is extremely urgent to prevent further isolation that will make them withdraw even more.
- The third task is to assist the aphasic person by encouraging their efforts to talk about things that really matter. If encouraged to express personal reactions and feelings, such as frustration and anger, they may find it easier to maintain integrity and identity. Others must not take rejections personally. When an aphasic person is angry the professional caregiver or the close relative has an opportunity to practice stepping back and analysing the situation.
- The fourth task concerns the importance of facilitating communication by helping nature and simply continuing to talk. During small talk it is important that the aphasic person is given enough time and that other disturbing factors are minimized. It can also be productive to complement words with gestures or written words if it helps to make understanding easier.
- The fifth task is to spare no efforts to understand the aphasic person's existential situation. This requires a reflective stance that makes it possible to find new creative methods to communicate that accord with the different types of aphasia. This is extremely important because regaining the ability to communicate can reduce humiliation and feelings of alienation and loneliness.
- The sixth task is to enable aphasic persons to recognize that theirself-images derive from the painful experience of losing the world of symbols. Inside they are the same as before, and it is important that others show that they recognize this. It is thus important for professional carers and close relatives, as well as personnel from community services, to reflect upon how to help the aphasic person to maintain a clearly defined self, by referring to their previous competence.
- The synthesising step in this study makes it reasonable to suggest that community service should include education in speech training and counselling on how to handle both practical and existential matters. Target groups for such measures are not only

aphasic persons and their close relatives but also the personnel employed by community services to support those families.

ABSTRACT

From the simplistic explanations of Wernicke's and Broca's, to the latest investigative headways made into the understanding of intricacies involved in the use of the spoken and written words; modern science is still in the process of understanding Aphasias. The use of radiological and pathological diagnostic modalities in the study of language deficits has helped in the recognition of two categories of aphasias. The acute and sub-acute presentations seen mostly in association with cerebrovascular accidents, CNS infections, and head trauma shows involvement of specific parts of the perisylvian language network which is located in the left hemisphere in majority of right as well as left-handed individuals. Based upon the evaluation of spontaneous speech, naming, comprehension, repetition, reading and writing, and diagnostic imaging these aphasias are divided into central aphasias and the disconnection syndromes. The central aphasias, namely Wernicke's and Broca's are due to damage of the two classical, though not anatomically discrete language centers bearing the same names. The disconnection syndromes are a result of damage to areas of the language network other than the classical centers and include Transcortical and Conduction Aphasias among others. The slowly progressive aphasias caused by neurodegenerative diseases are referred to as Primary progressive aphasias (PPA). In order to simplify understanding of these aphasias and thereby help find cures these aphasias have recently been classified into the agrammatic, semantic, and logopenic variants. Management and prognostic issues pertaining exclusively to language disruption are widely studied in the aphasias with actual presentation. The mainstay of treatment is speech and language therapy; however

some drugs are also showing promise especially when combined with language therapy. In post-stroke aphasic patients there is a strong correlation between initial severity and eventual recovery. Although most improvement occurs in the first few months, late language therapy has also shown benefit. Ongoing research also points to the potential utility of transcranial magnetic and electric stimulation for the treatment of certain aphasias.

INTRODUCTION

Aphasia is an acquired impairment of production or comprehension of language or both resulting from damage to the language network in the brain [1-3]. Beginning in the nineteenth century with the Dax's almost-forgotten theories and Broca's revolutionizing articles, our understanding of normal language and its impairment has come a long way [4, 5]. Although the concept of language centers is still found in clinical literature, it has been widely accepted that these centers are not circumscribed islands but various interconnected parts of the whole language network [6, 7]. In the majority of people, right-handed as well as left-handed (although to a lesser degree) this language network is located in the frontal, temporal and parietal Perisylvian areas of the left cerebral hemisphere [8, 9]. Aphasia secondary to lesions in the right hemisphere in right-handed individuals is rare and referred to as the Crossed aphasia [10]. It is worthy of notice that although impairments in the use of the spoken and written word have been vastly studied, however, the communication using gestures remains relatively less well incorporated into our overall understanding of aphasias [11].

CLASSIFICATION

The radiologic-pathologic correlation of the onset, progression and associated symptomatology of specific deficits in language perception and or production has led to the recognition of two broad but distinct clinical patterns of aphasia. The acute and sub-acute presentations are seen with directly or indirectly demonstrable involvement of specific parts of the left Perisylvian language network. These aphasias may be "central aphasias", resulting from damage to the two famous language centers, namely Wernicke's and Broca's, or the result of damage to areas of the language network other than the classical centers, the latter being termed the "Disconnection syndromes". [12, 13] On the other hand, chronic aphasias caused by neurodegenerative diseases show only atrophic changes on brain imaging and are dealt with under the umbrella term "Primary Progressive Aphasia" (PPA). The classification of PPA into the Agrammatic, Semantic, and Logopenic variants is a recent and important development to streamline efforts for the formulation of diagnostic criteria and management guidelines for this heterogeneous group of disorders [14].

The Classic Aphasias

These aphasias have been studied for over a century now and became the starting point of the intensive and revealing debate and research in the evolving field of the Aphasiology. They include Broca's, Wernicke's, Global, Conduction, Transcortical, Anomic and Subcortical aphasias.

1. Broca's Aphasia

Originally described by the French physician Pierre Broca in 1861, this is primarily a deficit in speech production with relatively preserved language comprehension [7, 15, 16]. Repetition and naming are impaired as well [16]. It must be borne in mind that comprehension is only relatively preserved and this becomes evident when the patient fails to understand long and complex sentences [7, 17].

The deficit in speech production is manifested by varying combinations of reduced phrase length, agrammatic sentence production, impaired melody of speech and decreased words per minute (10 to 15 words per minute compared to the normal rate of 100 to 115 words per minute) [6, 16, 18]. Spontaneous speech displays somewhat better utterance of generally familiar words e.g., *hi* and patients feel relatively better at singing a familiar song than at spontaneous speech [12, 18]. These deficits combine giving rise to the so-called telegraphic speech. In most severe forms there may be absolutely no understandable speech production with only one or few repetitive words or utterances accounting for the whole speech output. The patient is aware of the deficit, and the inability to convey the desired message via normal speech leads to visible consternation displayed by the patient's facial expressions and body gestures [12]. Despite the above mentioned speech output impairments, these patients generally succeed in conveying some part of the desired message, as the words which they do complete are clearly directed towards the specific idea or thought that is meant to be conveyed.

Neurological Damage and Causes

Broca's aphasia results from lesions involving the posterior part of the left Inferior frontal gyrus; this includes the Broca's area (Brodmann areas 44 and 45) and extends into adjacent parts of the Perisylvian frontal and Insular cortices [2, 16, 19].

The most frequent cause of this damage is embolic occlusion of the superior division of the left Middle cerebral artery (MCA) with the most typical neurological symptoms being displayed in the acute phase [19-21]. Other causes include hemorrhagic strokes and cerebral space occupying lesions (e.g., tumors and abscesses) affecting the same cortical areas [12].

Associated Features

As expected of impediments involving the superior division of left MCA, most cases are accompanied by right-sided upper limb and right-sided facial weakness. Damage which is exclusively limited to the Broca's area or some part of it results in purely motor articulatory impairments which have been referred to as Aphemia [2] or Apraxia of speech [16]. Due to its presentation Broca's aphasia has also been referred to as nonfluent, anterior, motor or expressive aphasia [18, 22, 23].

2. Wernicke's Aphasia

Originally described by the German physician Carl Wernicke in 1874, Wernicke's Aphasia refers to a primary deficit in both spoken and written language comprehension with paraphasic, neologistical yet fluent speech output [16, 24, 25]. Naming and repetition are impaired with repetition being as paraphasic and neologistic as spontaneous speech. Reading and writing skills are impaired as well [12].

These deficits in language comprehension and output are manifested by effortless, normally intoned spontaneous speech which is rendered relatively meaningless by excessive function words (pronouns, articles, prepositions etc.), paraphasias or word substitutions which may be full (semantic paraphasias e.g., fork for knife) or partial (phonemic paraphasias e.g., pyramid for pyramid) and utterance of neologisms or bizarre nonwords [2, 16, 18, 23]. These three defects combine giving rise to the so-called jargon speech [26].

These patients are unable to comprehend their own meaningless speech as well as others' speech and are at the same time totally unaware of this inability. In comparison with Broca's aphasia these patients may suffer anxiety but to a much lesser extent. Their frustration seemingly stems from others' inability to understand their speech, the incomprehensibility of which they are unaware of themselves owing to the lack of insight. Wernicke's Aphasia has also been referred to as fluent, posterior, sensory, or receptive aphasia [18, 22, 23].

Neurological Damage and Causes

Wernicke's aphasia results from lesions involving the posterior part of the left Superior temporal gyrus including the classically described Wernicke's area (Brodmann area 22) with damage usually extending into adjacent parts of the Supramarginal and Angular gyri of the left inferior Parietal lobe [26].

The most frequent cause of this damage is infarction of the inferior division of the left Middle cerebral artery (MCA) [16, 19].

Other causes include hemorrhagic strokes, severe head trauma and cerebral space occupying lesions (e.g., tumors and abscesses) affecting the same cortical areas [12, 18]. Wernicke's aphasia has also been reported as an outcome of patients presenting initially with global aphasia [27].

Associated Features

Most cases are accompanied by right homonymous hemianopia or right superior quadrantanopia [12].

3. Global Aphasia

This can be understood as a combination of the upper two aphasias and is characterized by profound involvement of all aspects of language perception and production including comprehension, spontaneous speech, naming, repetition, reading and writing [16].

Neurological Damage and Causes

Global Aphasia results from lesions involving large parts of the left Perisylvian language network including Broca's area, Wernicke's areas and adjacent parts of the inferior parietal lobule [16, 19].

It is usually caused by a large embolic occlusion of the left Less frequent causes include hemorrhagic strokes and cerebral space occupying lesions (e.g., tumors and abscesses) affecting the whole language network [18]. Transient global aphasia is also reported in postictal state, metabolic disturbances like hypoglycemia, hyponatremia and transient reversible stress induced cardiomyopathy. [18, 29, 137]

Associated Features

As expected of large occlusions involving the left MCA most cases are accompanied by right hemiplegia, right facial weakness and right homonymous hemianopia [2, 12].

Global Aphasia without Hemiparesis (GAWH)

This is an interesting uncommon clinical entity in which the patients show global language impairments without any facial and body weakness. GAWH has been reported with multiple embolic occlusions of various branches of the left MCA as well as with single large occlusions. Less frequent causes include hemorrhagic strokes and cerebral metastases affecting the language network [27].

4. Conduction Aphasia

Both Wernicke and Lichtheim hypothesized that the disruption of neuronal connections between the two language centers (Broca's and Wernicke's) would cause a distinct set of symptoms and Wernicke coined the term "Conduction Aphasia" [24, 30, 31] These patients have problems in repetition with meaningful, relatively fluent, slightly paraphasic (phonemic paraphasias [2]) speech with relatively intact comprehension of both spoken and written language [16]. The patient is aware of the problem and makes several attempts at self-correction characteristically, though not universally, producing a pattern termed "conduite d'approche" e.g., "*splant, plant, plants, pants*" for pants [16, 32]. Although naming, reading and writing tasks also disclose impairments, the impairment in repetition is markedly disproportionate.

Neurological Damage and Causes

In line with the earlier theories proposing damage to interconnecting pathways, it was believed that this aphasia is caused by damage to a white matter tract running between Wernicke's and Broca's areas called the Arcuate Fasciculus [33]. However the following considerations have led many specialists to search for other regions complicit in the causation of this aphasia:

- Damage to sites other than the Arcuate fasciculus including the left Superior temporal gyrus and the supramarginal gyrus has been demonstrated in conduction aphasic patients with a degree of consistency [34, 35].
- Multiple reports have been made of cases with repetition defects (one of the hallmarks of Conduction Aphasia) but with lesions sparing the Arcuate fasciculus [36, 37].
- Absence of conduction aphasia in patients with damaged or missing arcuate fasciculus [38, 39].

5. Transcortical Aphasias

Being any one of the sensory, motor and mixed varieties the Transcortical aphasias are characterized by relatively preserved repetition [2, 16]. Originally described by the German physicians Wernicke and Lichtheim, the Transcortical Aphasias were elaborated in detail by Goldstein who also referred to it using the phrase “isolation of the speech area” and traced the origin of the term “Transcortical” to Wernicke [40, 41].

A. Transcortical Motor Aphasia

With the exception of intact repetition, the motor variety is similar to Broca’s aphasia with nonfluent speech output and relatively intact language comprehension [2, 16].

Neurological Damage and Causes

This is most commonly seen in infarcts of the left anterior cerebral artery (ACA) or the left ACA-MCA watershed area which typically damage the regions surrounding Broca’s area thereby sparing or isolating it [16, 42, 43].

Associated Features

Signs which may give a hint towards the occluded portion in appropriate clinical settings include apathy and right sided hemiparesis [44].

B. Transcortical Sensory Aphasia

With the exception of intact repetition, the sensory variety is similar to Wernicke’s aphasia with fluent, paraphasic speech output and impaired comprehension of written and spoken language [2, 16].

Neurological Damage and Causes

This is most commonly seen in infarcts of the left Posterior cerebral artery (PCA) or the left PCA-MCA watershed territory resulting in isolation of Wernicke’s area [45].

Associated Features

Right visual field deficits may be seen in these cases [16].

C. Transcortical Mixed Aphasia

With the exception of intact repetition, this is quite similar to global aphasia [16].

Neurological Damage and Causes

This usually results from multiple emboli occluding the anterior (ACA-MCA) and posterior (PCA-MCA) cerebral watershed areas [46]. Other causes include anoxia and carbon monoxide poisoning [12].

Associated Features

As might be expected this aphasia may be accompanied by right Hemiparesis and/or right hemianopia [16, 46].

6. Anomic Aphasia

While naming difficulties of varying severities form part of the symptom-complex in various aphasias, “Anomic aphasia” is designated when naming of objects, persons, events, and things is selectively impaired, with comprehension, spontaneous speech, repetition, reading and writing skills being preserved [16, 47]. Although pure anomic aphasia is a rare entity interesting phrases like “word-finding difficulties” [48] and “tip-of-the-tongue” [49] situations have been used by experts to describe it. Owing to the specific defect in naming, spontaneous speech is fluent but circumlocutory and paraphasic [47]. The patient is aware of the deficit and shows obvious effort to find the correct words [48].

Neurological Damage and Causes

The part of the language network damaged has not been specifically localized. Different reports showing involvement of the left anterior inferior temporal lobe left middle temporal gyrus, and the left temporo-occipital junction have been made [48-51].

Anomic aphasia has mostly been attributed to head trauma, metabolic encephalopathy, strokes and brain surgery while Herpes simplex encephalitis has also been reported as a rare cause [12, 48].

7. Subcortical Aphasias

Aphasias have traditionally been considered a cortical problem [52]. Therefore the reporting of heterogeneous aphasias, defying the specific patterns described above, in patients suffering from subcortical lesions started an exciting new phase in this remarkable field of aphasiology [53-55].

While the specific role of subcortical structures in speech generation has been acknowledged, there have been studies which strongly raise the possibility that the cortical deficits in the presumed subcortical aphasic patients simply remained undetected due to the lack of modalities like SPECT, PET and advanced MRI at the time of reporting [52, 56-58].

Treatment and Prognosis of Classic Aphasias

While it can be said that much progress has been made in our understanding of aphasias, similar progress may not be claimed in the development of effective treatments for this disorder at this time.

Generally speaking any reversible causes of brain damage or dysfunction should be addressed first and foremost e.g., potential reperfusion of hypoxic brain tissue, treatment of any hypoglycemia or electrolyte imbalance, steroids for cerebral edema or possible surgical removal of any intra- or extra-axial mass lesions etc. Over time the development and co-existence of depression is common and should be regularly evaluated [59, 60]. Upon detection of depression or any other psychiatric illness expert advice and care might be required.

Since about a quarter to a third of stroke survivors suffer from aphasia it would not be surprising to find that aphasia outcomes and treatment approaches have been most widely studied in post-stroke aphasic patients [61, 62].

Various techniques and approaches are being studied and developed by neuroscience researchers, speech pathologists and therapists and neurologists aiming to cure or at least ameliorate this problem to an acceptable functional status.

Only language therapy is the validated treatment at present [63]. Pharmacologic interventions are being rapidly tested and transcranial stimulation (magnetic and electric) remains the least investigated potential treatment option for aphasic patients [64].

Intensive Speech and Language Therapy

Although showing variable effectiveness from highly to minimally effective in different reports, Speech and language therapy remains the mainstay of aphasia treatment [63, 65]. This therapy has especially been shown to be effective in the acute stage of the aphasia, although benefit has also been reported if it is started in the chronic stage [63, 66]. Moreover it has now been established that short-term intense therapy sessions have superior efficacy when compared to spread-out treatment plans [63, 67].

Customization of Therapy

Vascular aphasias present in various different forms varying in the type of disability as well as the severity. Coupling this with the diverse patient population coming from all the socioeconomic strata of society with their different possible minimal functional target levels creates a wide array of factors which have to be considered while instituting speech therapy.

The therapist and neurologist have the tedious task of making treatment regimens that will not only theoretically improve the functional status of the patient but also ensure compliance [68]. It is, therefore, imperative that the therapy be customized to the individual patient's needs, disabilities, motivation level and stamina [69].

Constraint-Induced Aphasia Therapy (CIAT)

As a natural response to this acquired disability aphasic patients adapt to the situation and develop strategies to bypass their deficits and exceedingly try to communicate via use of simplest possible phrases that they can utter or through gestures [70].

Though this is a clear attempt at self-rehabilitation, one harmful consequence of this reaction is the nonuse of all spared language abilities resulting in the actual recovery falling short of its full potential [71]. The aim of CIAT is to help the patient achieve highest levels of potential recovery. As the name indicates CIAT involves intense therapy sessions while minimizing the use of non-verbal communications. This approach seems to be very promising in efficacy as well as cost-effectiveness and needs to be studied at much larger levels [72-74].

Melodic Intonation Therapy

The use of music and singing sessions to improve speech output is being specifically studied in Broca's aphasia patients who demonstrate a lesser loss of singing skills at baseline as compared to spontaneous speech [12].

Pharmacologic Therapy

The manipulation of neurotransmitters in the brain especially in the regions surrounding the lesioned site seems to be a potential area of exploration for possible remedies [75]. However no agent has been unequivocally proven so far to be practically effective and safe in post-stroke aphasic patients [76]. Some drugs which might become useful in the future include:

- Piracetam combined with speech therapy has been shown to improve both speech production and comprehension [77].
- Donepezil is a cholinergic agent which has been shown to give sustained benefit up to six months after discontinuation [78].
- Memantine is an N-methyl-d-aspartate receptor antagonist with a good safety profile and has shown very promising results when combined with the already established CIAT [79].

Prognosis

The deleterious effects of aphasia on the life of the patient are both intensive and extensive. The disruptions caused in the patient's life range from the obvious problems in maintaining interpersonal relationships and meeting professional requirements to overt or covert depression in the patients themselves or in their caregivers [59,80,81]. At least some degree of recovery of language function is shown by a large majority of post-stroke aphasic patients [82]. Regardless of the specific type of aphasia left-handed individuals tend to show better recovery patterns than right-handed people [18] and sparing of Wernicke's area is associated with better outcomes [12].

Although occasional recovery has been shown to occur up to several years after the initial insult, significant spontaneous recovery has been shown to occur mainly within the first three months [78, 83, 84]. This also falls in line with the observation of some experts that maximum treatment benefit is also derived by instituting language therapy early in the course of the impairment [63, 66]. An interesting explanation put forth for this faster early recovery [85] is that the perilesional environment at that time, with its increased growth factor content, presents a promotive milieu for neuronal and synaptic recovery [86, 87].

A strong correlation exists between the severity of the initial insult and eventual recovery in most of the cases [88-90].

Primary Progressive Aphasia (PPA)

Primary Progressive Aphasia (PPA) is a clinical syndrome characterized by progressive language impairment with the conspicuous absence of other cognitive impairments like visuospatial or memory skills for the first two years and presence of only atrophic changes on imaging of the left perisylvian language network [14]. In essence the generalized foci of affected brain tissue dealt with in the classic aphasia are not applicable to PPA, which results

from perpetual neurodegeneration with simultaneous neuronal reorganization in the affected areas [14].

As may also be inferred from the preceding statement PPA is a disease of advanced age [91, 92]. Owing to the continuous increase in life expectancy [93] and its implicit health care cost burden [94], definitive diagnosis and treatment of this entity has become an object of paramount importance for neurological experts as well as health care administrators and policy makers.

PPA has been further categorized into three distinct variants.

1. Agrammatic Variant (PPA-G)

The characteristically encountered problems in this variant include slow spontaneous speech with [14, 95-97]:

- Anomia.
- progressive inability to produce properly structured sentences, the sentences being devoid of the small words (“determiners”) that precede nouns in normal speech, like *the professor, a school, a bit of mustard, that lady*.
- Improper word-order in sentences.

These combined with the initially less obvious decreasing speech fluency lead to considerable disability over time. However, it is noteworthy that even in the advanced stages of the condition there is relative preservation of comprehension. Patients are aware of their language impairment [98-99].

Imaging Characteristics

Following patterns of atrophic changes have been noted:

- In the left posterior inferior frontal gyrus (Broca’s area), Insula, premotor and supplementary motor areas [100].
- A smaller proportion of cases have shown generalized left perisylvian atrophy [101].
- Normal neuroimaging has also been reported [102].

Neuropathology

This is variable, however, histopathology of a number of cases of PPA-G demonstrates patterns consistent with Pick’s disease or corticobasal degeneration (CBD) pathology with neurons containing a microtubule-associated protein tau (MAPT) [102, 103].

Associated Features

Many cases with agrammatic variant of PPA show extra pyramidal features of corticobasal degeneration (CBD) and progressive supranuclear palsy (PSP) [104, 105] e.g., bradykinesia and gaze palsy during the course of the disease. Limb apraxia has also been reported [106].

PPA-G may also be referred to as nonfluent variant PPA (nfvPPA) [91] or Progressive nonfluent aphasia (PNFA) [107].

2. Semantic Variant (PPA-S)

Semantics is the study of meanings of word [108]. Severe progressive anomia is the hall mark of this variant which is a direct consequence of the loss of meanings of words [109]. Patients tend to ask the meanings of words repetitively [110] but lack insight of their impairment [99]. Speech fluency and repetition is preserved. With progression of the semantic deficits, object recognition through sensory inputs other than speech is also impaired leading to inability to recognize smells (olfactory agnosia) [111], and inability to visually recognize objects (visual agnosia) [110] which may eventually lead to disturbance in facial recognition (progressive prosopagnosia) [112].

Imaging Characteristics

Selective atrophic changes affecting the anterior temporal lobes bilaterally, being more severe on the left, are characteristic of PPA-S [113-116].

Neuropathology

Most PPA-S cases have shown the histological picture of ubiquitinated frontotemporal lobar degeneration (FTLD-U) pathology with ubiquitin positive, tau-negative inclusions [117, 118].

Associated Features

PPA-S has a strong association with the behavioral or frontal variant of Frontotemporal (bvFTD) [119, 120]. There is marked disinhibition [121], increased social seeking [120] and extreme changes in food preferences [121] (the food fads [120]) leading at times to weight gain [121].

PPA-S may also be referred to as Semantic variant PPA (svPPA) [100], primary progressive semantic aphasia [122], fluent PPA [123], or temporal variant FrontoTemporal Dementia [124] and was originally named semantic dementia (SD) [125].

3. Logopenic Variant (PPA-L)

This is the most recently recognized variant of PPA [115] and displays some features of both the other variants [126]. Spontaneous speech is slow like PPA-G but unlike it, is free from major agrammatic errors [95]. The naming impairment is less severe than PPA-S, and the meanings of words are not lost [95]. As suggested by preserved repetition of single words and impaired sentence repetition, short-term phonologic memory losses have been hypothesized to be the basic mechanism of aphasia in these patients [127].

Imaging Characteristics

Atrophic changes are seen in superior and middle temporal gyri posteriorly and in the inferior parietal lobule [115]. There have been recent reports of involvement of the left medial temporo-parietal cortex, right temporo-parietal cortex, and left inferior frontal cortex accompanied by corresponding white matter atrophy in these regions as well [127-129].

Neuropathology

PPA-L has been shown to be strongly associated with the Alzheimer's disease (AD) pathology [12].

Associated Features

Behavioral abnormalities like apathy, anxiety, and irritability may be seen [119, 129].

PPA-L may also be referred to as the Logopenic variant PPA (lvPPA) [91], Logopenic Progressive Aphasia (LPA) [115] or progressive mixed aphasia [14, 102, 130].

Treatment and Prognosis of PPA

The clinical utility of speech and language therapy has not been studied enough to warrant the formulation of standard guidelines for PPA, however, a beneficial role does seem probable [131]. Similarly the use of pharmaceutical agents is also only in the early stages of exploration [91], although Memantine has shown to be of potential benefit in the agrammatic variant (PPA-G) [132].

The established interventions include education, counseling and support for the patient and caregivers along with the medical amelioration of associated behavioral symptoms e.g., prescribing Selective Serotonin Reuptake Inhibitors (SSRI) for agitation and food-fads [91, 133].

There is an acute shortage of epidemiological data for PPA [134]. What we do know is that PPA demonstrates a slow yet steady progress in language deterioration [14] which might start out as any one of the three variants but gradually goes on to show a mixed picture with extensive overlap between variants [91]. This deterioration remains confined to the language domain in the initial years but this might be the case for up to ten years [12]. Patients survive for an average of eight to ten years after diagnosis [105, 135] almost invariably dying of other diseases of old age [136].

CONCLUSION

The Aphasias, both classic and progressive, continue to take an enormous toll on human health and functionality. Present research points to the number of potential cures which need to be studied on larger scale over longer periods of time for the development of cost-effective strategies in preventing and curing this debilitating condition. Any breakthrough in developing an effective treatment for one category of aphasia may well be beneficial for other types as well. The treatment, management and understanding of the disease pathophysiology of aphasia remain a challenge in the coming years.

ABSTRACT

Aphasia after stroke is a common and disabling symptom, which can recover in the weeks, months or years following brain injury, showing that the adult brain can reorganize to adjust to impaired functions. Standard rehabilitation approaches aim to improve the deficient function through speech and language therapy (SLT). In parallel with increasing knowledge about central nervous system plasticity, different adjuvant interventions have been recently implemented to enhance the outcome of speech and language therapy. One of them consists in increasing the intensity of SLT in order to obtain better recovery. This is achieved for instance with computer-assisted therapy (CAT) or with constraint-induced aphasia therapy (CIAT) approaches.

A second approach tested the combination of a number of drugs with SLT, with the aim to increase its effect. The mechanism thought to underlie enhanced recovery with the addition of specific drugs includes increasing attention and learning through modulation of neurotransmission or restoring metabolic function. Several substances have been assessed, including noradrenergic drugs and drugs acting on the dopaminergic, glutaminergic, gabaergic, and cholinergic systems.

Finally, another, still experimental, intervention in stroke rehabilitation consists of neuromodulation via non-invasive cortical stimulation, e.g., through transcranial magnetic stimulation (TMS) or direct current stimulation (tDCS). These techniques have recently been proposed to potentially endorse functional recovery after stroke through (i) enhancing excitability of the stroke hemisphere or (ii) suppressing the non-stroke

hemisphere to reduce its potential interference with functional recovery of the stroke hemisphere.

While both treatment intensity and TMS have led to several promising results on efficacy in aphasia rehabilitation, the effect of pharmacotherapy seems to be less straightforward. In the present chapter we will perform a review of recent literature on the effects of these approaches as potential adjuvant to standard SLT in the rehabilitation of aphasia.

ACRONYMS

AAT:	Aachen aphasia test
CAT:	computer-assisted therapy
CIAT:	constraint-induced aphasia therapy
CILT:	constraint-induced language therapy
NMDA:	N-methyl-D-aspartate
PICA:	Porch index of communication ability
RCT:	randomized controlled trial
SLT:	speech and language therapy
rTMS:	repetitive transcranial magnetic stimulation
tDCS:	transcranial direct current stimulation
WAB- AQ:	Western aphasia battery- aphasia quotient

INTRODUCTION

Aphasia can occur in association with a wide range of brain injury and represents a common severe cognitive consequence following stroke as incidence of aphasia in stroke patients has been estimated around 30% (Engelter, Gostynski et al. 2006).

Spontaneous recovery can be expected in the acute phase by reperfusion of partially damaged tissue, resolution of edema, then resolution of diaschisis. In the sub-acute phase, reorganization within undamaged areas has been observed both in perilesional tissues in the left hemisphere and homologue areas in the right hemisphere (Saur and Hartwigsen 2012).

Speech and language therapy (SLT) is a generally accepted treatment modality for aphasia following stroke (Cicerone, Dahlberg et al. 2005). Rehabilitation training with SLT aims to achieve functional reorganization through plasticity in view to enhance functional outcome. However, efficacy and outcome of SLT are not always optimal (Kelly, Brady et al. 2010). That's why research still needs to address which conditions allow to optimize SLT and its outcome. In the present chapter we will briefly review SLT conditions known to optimize its efficacy, in particular treatment intensity, before describing an overview of some very different potential adjuvant to SLT, namely computer assisted treatment, pharmacotherapy and transcranial magnetic or electric stimulation.

LEARNING AND PLASTICITY

As a matter of fact neural plasticity that supports learning in healthy subjects is also the adaptive mechanism which allows reorganization to restore or compensate lost functions (“relearning”).

Neural plasticity includes molecular modifications (e.g., changes in gene expression), cellular modifications (for example dendritic growth), synaptic modification (synaptogenesis, increased synaptic responses, long term potentiation), circuit modification with reorganization of representation (cortical map reorganization) and finally change in activation patterns-neural connectivity (Raymer, Beeson et al. 2008), (Kleim and Jones 2008).

Acknowledging the diversity of these underlying processes is important because of their direct implication in rehabilitation. We will briefly mention a few of them.

1. Lack of activation of specific neuronal circuits leads to synaptic weaknesses and it constitutes the basis of the “learned non use”. The typical example is a patient with arm paresis who avoids using it, preferring the unaffected arm. A specific intervention has been suggested to avoid “learned non use” in the motor domain, namely “constraint induce therapy”, first developed by Taub and colleagues (Taub, Uswatte et al. 1999) which consists of restraining the unaffected limb to limit its use and a training program for the affected limb. Similarly, a patient with aphasia might avoid verbal communication, replacing it with gestures and pointing or restricting verbal communication to a limited set of utterances. The aim of this kind of intervention in the language domain would be therefore to force the patient to use all his residual language skills (constraint induced aphasia therapy (CIAT), (Pulvermuller, Neininger et al. 2001).
2. It is arguable that treatment focused on one particular aspect of language would have a different result according to the SLT approach (Thompson 2000). The lack of generalization to untreated items (treatment specificity) has been shown in various treatment studies and in particular in anomia studies, where the improvement in naming is restricted to the treated items (Laganaro, Di Pietro et al. 2006). The number and the choice of treated items are therefore important.
3. There is some evidence that action and perception systems co activate with the language system. For example reading action verbs activated a somatotopic pattern within premotor and motor cortex (Hauk, Johnsrude et al. 2004). Because of this interaction, relevant context may possibly facilitate language processes (Pulvermuller and Berthier 2008).
4. Salience is important: the more the stimulus has salient “weight” for the subjects (for example in animal model stimuli allowing reception of a reward), the easier it is encoded. The basal forebrain cholinergic system probably contributes to saliency (Kleim and Jones 2008) and cortical plasticity (Conner, Chiba et al. 2005) and has lead to the introduction of pharmacological treatment based on anti cholinesterase drugs. Moreover, dopamine, seems to mediate the incentive salience of a reward and plays a role in motivation (Berridge and Robinson 1998).
5. Finally learning is driven by correlation. The more frequently a neuronal circuit is activated in a synchronous manner, greater the synaptic strengths. The importance of

intense (quantity) and high frequency treatment for aphasia is derived from these underlying learning processes (Berthier and Pulvermuller 2011) and it is discussed below.

In sum, a series of neurobiological mechanisms contribute to brain plasticity and relearning. Efficient SLT may rely on some of them more specifically; alternatively, some adjuvant treatments may improve the effects of SLT by priming or optimizing the underlying neurobiological mechanisms.

TREATMENT INTENSITY

As mentioned above, based on the way repetition strengthens synapses, treatment intensity seems to have a critical impact on recovery.

As a matter of fact in a meta analysis including published research between 1975-2002 (Bhogal, Teasell et al. 2003), the authors concluded on no effect of SLT in studies in which 2 hours weekly sessions of SLT were provided over a period of 22, 9 weeks, whereas significant effects of SLT were observed when an average of 8,8 hours of weekly therapy was provided over 11, 2 weeks. Not only the total number of therapy hours but also the number of weekly sessions (“massed practice”) was significantly correlated to greater improvement on language assessment tests (Bhogal, Teasell et al. 2003). A systematic review of the Cochrane group including 30 trials between 1966 to April 2009 also found consistent evidence in favor of effectiveness of intensive SLT (Kelly, Brady et al. 2010), although Cherney and colleagues make more cautious conclusions in an another systematic review (Cherney, Patterson et al. 2011).

Furthermore, treatment intensity can be modulated not only by increasing the total number of SLT session but also in terms of number of treated items and item repetition (drill) during therapy and finally in terms of massed practice, namely sessions grouped over a short period rather than distributed over a longer time period. Increasing SLT intensity is not always possible due to a series of limitations in the health-care system (manly due to costs), but there are a few alternative/adjuvant ways to increase treatment intensity. Among these methods constraint-induced aphasia therapy (CIAT) and computer-assisted therapy (CAT) will be presented in the following section.

CONSTRAINT-INDUCED APHASIA THERAPY

In constraint-induced aphasia therapy (CIAT) (Pulvermuller, Neininger et al. 2001) intense massed practice is combined with forced verbal language use. It consists of a therapeutic game activity carried out in small groups of aphasic patients with a therapist. The “game” is played with a set of cards with pictures on it, including two identical copies of each card. The task is to explicitly request the second card from another player. All requests have to be performed with verbal language. Shaping is performed by new explicit rules including the requirement to use the name of the co-players, politeness formulas, determiners, and so on.

In a randomized controlled trial Pulvermüller et al. compared two groups of chronic aphasic patients with the same amount of treatment but either massed over 10 days of 3 hour sessions of CIAT, or 4 week of conventional therapy. Significant improvement on 3 different clinical tests (naming, comprehension, Token test scores) was reported in the CIAT group and limited improvement in the control group. In addition, improvement in everyday communication was only observed in the CIAT group, (Pulvermüller, Neining et al. 2001).

Further studies replicated the efficacy of CIAT (30 hours of training over 10 days) to improve language function in a larger sample of chronic aphasic patient (27) and results were stable at a 6 month follow up assessment (Meinzer, Djundja et al. 2005).

Maher and colleagues compared constraint-induced language therapy (CILT) defined as limiting the response only to spoken verbal production with promoting aphasic communicative effectiveness (PACE) therapy allowing all modes of communication, in a dual card game. Both groups received the same amount of therapy (3 hours, 4 days a week during 2 weeks) but they were not randomized. Positive results were observed in both groups but there was more consistent improvement in the CILT group on standard measures and on some aspects of narrative discourse (Maher, Kendall et al. 2006) showing that intensity is not the only important factor.

In a review of 10 studies (Cherney, Patterson et al. 2008) and in a recent review (Meinzer, Rodriguez et al. 2012) the authors conclude that there is indeed evidence of beneficial effects of CIAT on language functions. However, the reviews also outlined that the relative contribution of each of the aspects of CIAT (particularly massed practice and constraint verbal use) need to be further investigated (Meinzer, Rodriguez et al. 2012). Other studies concluded to limited effects of CIAT which were not maintained 3 months after treatment (Farooqi-Shah and Virion 2009).

COMPUTER ASSISTED THERAPY

An alternative way of increasing treatment intensity is implementing computer assisted therapy (CAT). CAT has several practical advantages for SLT, ranging from the possibility of increasing treatment intensity in terms of number of sessions and drill to a larger involvement of patient in therapy with increased autonomy and the possibility of controlling several parameters of stimuli presentation and feed-back.

CAT has been introduced since the 1980s in aphasia treatment, but a first review published in 1990 concluded that these first attempts did not prove its efficacy (Robertson 1990). In later years an increased number of studies have investigated the efficacy of CAT. As for other SLT approaches, most CAT studies targeted anomia treatment in aphasic patients (Fink, Brecher et al. 2002), (Laganaro, Di Pietro et al. 2003), (Pedersen, Vinter et al. 2001) and a few of them targeted other domains such as sentence comprehension (Crerar, Ellis et al. 1996), agraphia (Mortley, Enderby et al. 2001) and alexia (Laganaro and Overton Venet 2001). As a consequence, a second review on CAT published in 2004 concluded that several studies have proved the efficacy of CAT when specific linguistic domains are targeted (Wertz and Katz 2004). CAT studies have been shown to improve recovery from aphasia in chronic patients, but also in studies carried out with patients in the post-acute stage. In the latter studies, CAT sessions have been added to standard SLT sessions (Laganaro, Di Pietro et al.

2006). As a consequence, CAT allowed increasing treatment intensity from one to two daily sessions. Alternatively, CAT can also be delivered at home (Mortley, Wade et al. 2004), also allowing high intensity treatment. As an example, in a single patient study by Laganaro and Overton (2003), the patient worked at home daily on average 70 minutes during 3 weeks on a CAT for alexia. Finally, CAT enables intensity in terms of increased item-repetition (drill), which is also an essential condition for (re-)learning (see above). In a study on CAT for anomia, each of the 8 patients who received CAT with the same program repeated each item the number of times they estimated necessary, which varied from 5 to 21 times (Laganaro, Di Pietro et al. 2006a); in another study including patients presenting with similar anomia severity at baseline, each of the 3 patients achieved 85% of accuracy after a number of sessions varying from simple to double (Laganaro, Di Pietro et al. 2006b). These two examples illustrate how CAT also enables the adaptation of treatment intensity in terms of drill and of number of sessions for individual patients.

PHARMACOLOGICAL TREATMENT

Rationale for pharmacological treatment of aphasia is based mostly on two purposes: strengthening neural activity in networks mediating attention, word learning and memory and reestablishing the activity of neurotransmitters in dysfunctional brain region (Berthier, Pulvermuller et al. 2011).

Several substances have been assessed in studies with aphasic patients, including drugs acting on the noradrenergic, dopaminergic, glutaminergic, gabaergic, cholinergic systems. We will briefly review each of these groups of drugs.

Noradrenergic

D-amphetamine (or Dexamphetamine or Dextroamphetamine)

D-amphetamine acts mainly on the noradrenergic and dopaminergic systems and therefore possibly increases general brain excitability. After experimental infarction in rats it enhances neurite growth and synaptogenesis (Stroemer, Kent et al. 1998). Several studies have been published about the effect of amphetamine in combination with physiotherapy in motor recovery with a trend towards greater improvement in the amphetamine group (Sonde and Lökk 2007).

D-amphetamine has been found to enhance language learning in healthy subjects (Breitenstein, Wailke et al. 2004), (Whiting, Chenery et al. 2008). D-amphetamine has also been explored to favor recovery in aphasic patients. A double-blind placebo controlled study has been carried out with 21 stroke aphasic patients in the post-acute stage receiving 10 mg of dextroamphetamine or placebo, 30 min before speech therapy during 5 weeks. The authors reported that amphetamine paired with speech therapy accelerated immediate recovery from aphasia on the Porch Index Communication Ability (PICA), but at 6 months no significant difference was found between the two groups (Walker-Batson, Curtis et al. 2001).

A smaller placebo-controlled, crossover design, shows that 2 chronic aphasic patients correctly named treated items more accurately under amphetamine than under placebo but the gain was statistically significant in only one patient (Whiting, Chenery et al. 2007).

However in clinical practice the administration of amphetamines is limited by the potentially serious side effects notably on blood pressure (Martinsson, Hardemark et al. 2007).

Dopaminergic

Dopamine contributes to synaptic plasticity (including long term potentiation) in different brain areas (hippocampus, striatum and prefrontal cortex) and seems to be a regulator in synaptic changes observed in learning and memory (Jay 2003). Different substances can act on the dopaminergic system, including levodopa (dopaminergic precursor), bromocriptine (dopaminergic agonist), moclobemide (monoamine oxydase inhibitor), and amantadine (dopamine releaser).

Levodopa

Some studies have shown an effect of levodopa on motor learning in young healthy volunteers and elderly subject (Floel, Breitenstein et al. 2005) and in patients following a stroke (Rosser, Heuschmann et al. 2008), (Scheidtmann, Fries et al. 2001). For instance, Levodopa as compared to placebo accelerated and improved word learning in 40 healthy subjects (Knecht, Breitenstein et al. 2004).

In aphasic patients, two randomized double blind placebo-controlled studies reported contradictory results in the acute phase, using similar doses of levodopa (100 mg) during 3 and respectively 2 weeks. In one study with 19 subjects, larger improvement was observed in the patients receiving levodopa than in the placebo group in three subtests of the Boston diagnostic aphasia examination: animal naming (verbal fluency), sentences and words repetition (Seniow, Litwin et al. 2009). By contrast in the other study, involving 12 patients, levodopa did not modulate the amount of improvement obtain with therapy (CAT) (Leemann, Laganaro et al. 2011).

In conclusion the potential effect of levodopa on recovery from aphasia remains controversial, even if it is postulated that disruption of dopamine pathways may play a role in distinctive features of non fluent aphasia (Berthier 2005).

Bromocriptine

A few single and multiple case reports and open label trials using bromocriptine reported improvement in language performance in non fluent chronic aphasic patients: 1 patient increased his naming accuracy and then returned to baseline after discontinuation (Albert, Bachman et al. 1988), 3 out of 7 patients (those with moderate aphasia) showed significant improvement on a lexical index and verbal fluency task, but also only the time the drug was given, (Sabe, Leiguarda et al. 1992), and 4 patients experienced significant increase in word retrieval, followed by a decrease after withdraw (Gold, VanDam et al. 2000).

In a randomized double blind placebo-controlled study on chronic non fluent aphasic patients, bromocriptine combined with SLT improved in particular verbal latency, reading

comprehension, and qualitative measures of spontaneous speech in 5 patients (Bragoni, Altieri et al. 2000). The principal limitation of this study is that many patients were excluded during the recruitment phase (14 out of 25) and there was also a high rate of dropouts (6 of 11) due to secondary effects. Here again the effect on verbal latency was not sustained after wash-out.

Efficacy of bromocriptine in non fluent aphasia was not confirmed in one open label trial (Ozeren, Sarica et al. 1995) and in three randomized double blind placebo-controlled study, as well in the acute phase on 38 patients with maximal dose 10 mg /day (Ashtary, Janghorbani et al. 2006) as in studies carried out in the chronic phase with different doses (Gupta, Mlcoch et al. 1995) (Sabe, Leiguarda et al. 1992). Nevertheless the major limitation of these last two studies is that no SLT was given during the trial period.

In summary bromocriptine in chronic non fluent aphasia, associated with SLT, has a possibly, but not lasting, effect on verbal latencies.

Moclobemide

No difference between moclobemide (daily for 6 months) and placebo has been reported with a large (90 patients) double blind, placebo randomized study, with patients in the acute stage (Laska, von Arbin et al. 2005).

Amantadine

Amantadine increases the release of dopamine and norepinephrine but has also anti cholinergic proprieties and weak antagonism of NMDA receptor (Berthier, Pulvermuller et al. 2011). An open label trial in 4 transcortical motor aphasic patients, using multiple assessments during on –off drug periods suggested that amantadine paired with SLT improves performance in a word generation task (Barrett and Eslinger 2007).

Piracetam (Pyrrolidone Acetamide)

Research on piracetam showed an effect in a variety of neurological disorders with some effects on memory, attention, cognition and depression (Malykh and Sadaie 2010).

The exact mechanism by which piracetam acts to improve these functions is unknown because piracetam is a non-specific pharmacological agent which seems to have a role in energy metabolism, particularly through its effect on cell membrane, a gaba-mimetic action, and its activation of AMPA-type glutamate receptors (Malykh and Sadaie 2010). It enhances also neurotransmission of acetylcholine (Huber 1999),(Berthier and Pulvermuller 2011).

They are many studies using piracetam in the acute phase after stroke including several studies on aphasia. Enderby et al. performed a 12 week, double blind, parallel randomized placebo-controlled study with 158 post stroke patients, including 67 with aphasia. Patients also received SLT although its type and intensity was not mentioned. Higher improvement was reported for the piracetam group relative to the placebo group on several language assessment tests, but these benefits were not maintained 24 weeks later (Enderby, Broeckx et al. 1994).

A very large (N=927 stroke patients) multicenter RCT including a subgroup of aphasic patients evaluated the effectiveness of piracetam provided early after stroke during 12 weeks (De Deyn, De Reuck et al. 1997). Recovery from aphasia was particularly high in the group

of patient treated within 7 hours post onset (Orgogozo 1999),(Huber 1999). However aphasia was not investigated in details but only documented with screening tests.

In a RCT including 66 aphasic patients, piracetam or placebo was associated with SLT during a 6-week period. In the piracetam group a significant effect was reported on the written language subtest of the Aachen aphasia test (AAT) (Huber, Willmes et al. 1997).

In another RCT study involving 24 aphasic patients within 14 days post stroke, piracetam or placebo were also given for 6 weeks in conjunction with SLT. Both groups displayed some improvement in token test, AAT subtest for written language and comprehension but the piracetam group also showed significant improvement in spontaneous speech (Kessler, Thiel et al. 2000). On the other hand there was no clear beneficial effect of piracetam in a RCT of 49 aphasic patients receiving 4800 mg of piracetam or placebo during 6 months. However, there was no intensive SLT associated to pharmacotherapy in this study and only 30 of the 49 patients were finally analyzed (Gungor, Terzi et al. 2011).

In sum, piracetam seems to be an effective treatment of aphasia in combination with SLT when given in the acute phase post stroke and has a low incidence of mild adverse events (Noble and Benfield 1998).

Glutaminergic

Glutaminergic over activation of N methyl D aspartate (NMDA) receptors results in intercellular calcium overload, causing some neuronal dysfunction and death. Therefore one of the rational to use N methyl D aspartate (NMDA) glutamate receptor antagonist is the expected neuroprotective effect. Memantine, a NMDA receptor antagonist versus placebo has been investigated in a RCT with 27 chronic post stroke aphasic patients. The memantine group displayed higher improvement than the placebo group and recovery was even greater when speech therapy CIAT was added (Berthier, Green et al. 2009).

On the other hand, recently it has been demonstrated that hyper activation of NMDA is then followed by prolonged decrease in NMDA function. Thus perhaps stimulation –and not antagonism- of NMDA could be useful (Dhawan, Benveniste et al. 2011).

Cholinergic

On the basis of the role of the basal forebrain cholinergic system in motor learning and memory (Conner, Culbertson et al. 2003), in saliency (Kleim and Jones 2008) and based on the experience with Alzheimer disease (Hansen, Gartlehner et al. 2008) different cholinesterase inhibitors have been tried with aphasic patients (Berthier, Pulvermuller et al. 2011).

In an open label study cholinergic agent donepezil was administered to 11 chronic post stroke aphasic patients: improved performance on the WAB-AQ was reported after 4 and 16 weeks but then declined with washout (Berthier, Hinojosa et al. 2003).

In another small open label study of 4 patients, the 2 patients receiving bifemelane increased their language scores (Tanaka, Miyazaki et al. 1997).

A double-blind, RCT combining donepezil versus placebo and SLT in 26 chronic aphasic patients, also showed a significant benefit of the donepezil group on language and communication measures (Berthier, Green et al. 2006).

Gabaergic

There is an anecdotic report of a chronic aphasic woman who improved transiently but, repetitively and dramatically her speech after zolpidem, an agonist of GABA receptor (Cohen, Chaaban et al. 2004).

In conclusion, despite evidence from basic science that certain drugs can promote plasticity, pharmacological intervention in aphasia has not conclusively proved its effectiveness; this is due mainly to poor study design, including patients with different types of aphasia and not using or describing homogeneous SLT associated with pharmacotherapy.

The time window of drug administration after stroke is probably important: in the acute phase preference would be given to drugs with neuroprotective effect or with the potential to reestablish metabolic function whereas in the chronic phase preference would be given to drugs improving learning. Also, it seems that drugs should be given in association with SLT in view to obtain synergy between drug and behavioral therapies.

TRANSCRANIAL MAGNETIC AND DIRECT CURRENT STIMULATION

Another approach to SLT consists of favoring neuromodulation with transcranial brain stimulation. This kind of intervention has been carried out using non-invasive stimulation, such as transcranial magnetic or direct current stimulation. Although this kind of approach is still experimental at least regarding therapy for aphasia, a few studies have proposed transcranial stimulation with stroke patients either to suppress the potential inhibitory effect of the contra-lateral hemisphere or to enhance the excitability of perilesional areas. Here we will briefly review the outcome of studies using transcranial magnetic stimulation (TMS) or direct current stimulation (DCS) with aphasic participants.

TRANSCRANIAL MAGNETIC STIMULATION (TMS)

TMS is a non invasive technique consisting of a brief pulse of current flowing through a coil of wire and generating a magnetic field, which induces a physiological response in targeted brain regions. TMS applied repetitively (rTMS) can either inhibit or excite cortical activity depending on its frequency and intensity. Brain stimulation is used to increase cortical excitability aimed at facilitating long term potentiation like processes; inhibition is applied to the contralesional hemisphere in the aim to facilitate the ipsilesional hemisphere activity.

As excitatory high frequency TMS has safety issues in stroke patients (Tassinari, Cincotta et al. 2003), TMS has been applied mainly at low frequencies (1Hz) in order to disrupt locally cortical activity at right hemisphere areas potentially interfering with recovery in aphasic patients.

Preliminary experiments applied rTMS to suppress the unaffected right hemisphere in a small group of non-fluent aphasic patients (Martin, Naeser et al. 2004). These studies showed improvement in specific language production tasks, in particular when stimulation targeted the right Broca homologue area. The effects persisted two months after a 10 day treatment. The benefit in recovery has been assigned to a release of the affected left hemisphere from right hemispheric inhibition (Pascual-Leone, Amedi et al. 2005), (Bolognini, Pascual-Leone et al. 2009). Crucially, in the study by Naeser et al. improvement was observed only after stimulation of the right Broca homologue area, not after stimulation of right temporal areas. However, other studies have shown differential effects on a picture naming tasks when suppressing the right pars triangularis versus the right pars opercularis of the inferior frontal lobe (Naeser, Martin et al. 2011) or facilitative effects when excitatory stimulation was applied to these areas (Winhuisen, Thiel et al. 2005), suggesting a right hemispheric contribution to language recovery and questioning the general applicability of the inhibitory TMS approach (Turkeltaub, Coslett et al. 2011).

DIRECT CURRENT STIMULATION

Transcranial direct current stimulation (tDCS) is also a non-invasive brain polarisation technique that modulates the cortical excitability using weak direct currents. Depending on the polarity of the direct current (anodal vs. cathodal) it increases or decreases brain excitability. Although its spatial and temporal resolution is lower than TMS, it is often preferred because it is safer and easier to use than TMS. In a few studies anodal tDCS applied to left perilesional areas showed positive effects on accuracy and latencies in picture naming tasks (Baker, Rorden et al. 2010), (Fridriksson, Richardson et al. 2011). Fridriksson et al. (2011) applied anodal tDCS to left perilesional areas in association with computer-assisted therapy (CAT) sessions for anomia in eight chronic aphasic patients. They reported a decrease in production latencies relative to CAT sessions without tDCS. However, improvement has also been reported immediately after 10 minutes of tDCS without associated SLT (Monti, Cogiamanian et al. 2008). In this study cathodal tDCS applied to the left fronto-temporal areas in chronic non-fluent patients increased picture naming accuracy. The authors interpreted these results as an effect of decreased excitability of abnormal cortical inhibitory circuits. Alternatively, tDCS was applied to the right inferior frontal cortex (Vines, Norton et al. 2011). The authors investigated the effects of anodal tDCS in six chronic patients with non-fluent aphasia. tDCS stimulation was associated with three sessions of melodic intonation therapy. They reported greater improvement after the anodal tDCS relative to the therapy sessions without tDCS (sham).

In sum, both TMS and tDCS studies have shown some promising results in inducing long-lasting plastic changes and recovery in aphasic patients. So far, most studies have been conducted with chronic aphasic patients. At present however it is far from clear which brain areas should be targeted with excitatory vs. inhibitory stimulation. Actually, the type of SLT

associated with cortical magnetic or electric stimulation or even inter-individual variability may modulate the choice of the targeted brain area, and this approach clearly needs additional empirical evidence before an extended application in clinical practice.

CONCLUSION

The basic knowledge of brain plasticity has grown but the exact mechanisms underlying recovery from aphasia are for the moment not fully understood and are a limit for the development of therapeutic option.

However today with certain evidence, a few recommendations can be retained.

The current practice of spreading SLT over a long period should be modified and short intensive treatment (massed practice) is preferred. There are a few methods which are indicated to increase treatment intensity: we have reviewed two of them: CIAT and CAT. These two treatment approaches have proved their efficacy and are certainly good candidates to address the issue of providing intensive treatment without increasing health costs. In all cases treated items in SLT should be chosen carefully because of the lack of generalization to untreated linguistic material and structures and the importance of having a relevant treatment.

Other approaches have emerged to facilitate neural plasticity and therefore improved treatment effects or recovery. Despite some encouraging results, these techniques still need to prove their efficacy. Importantly, if pharmacological or brain stimulation approaches are used, they should be coupled with adequate SLT, as they probably prime (re)learning, and learning cannot be achieved without training.

In sum, clinical practice has evolved during the past 20 years in several different directions to optimize SLT and its outcome; but most of these options still need to be better defined and developed.

ABSTRACT

Language impairments are frequent in stroke, especially in the hyper acute phase, occurring in 15 to 50% of stroke patients. Recovery from aphasia remains difficult to predict. Language impairment still exists in at least 50% of initially aphasic patients one year after stroke. Post-stroke aphasia is a major source of disability that can lead to impaired communication, reduced social activities, depression and a decreased likelihood of resuming work. The role of the stroke unit in improving morbidity, mortality and recovery has been clearly demonstrated. Nevertheless, the need for intense and sustained acute management of aphasia in specialized stroke units remains controversial. The recent validation of a tool to rapidly screen for aphasia (LAST) after stroke allows for its early detection and management. Early detection of aphasia after stroke may improve outcomes by taking advantage of the synergy between intensive speech therapy and early neural reorganization. Daily re-evaluation will facilitate tailored rehabilitation sessions, multidisciplinary management by the stroke team, and development of educational resources for patients and their caregivers. Standardizing protocols for identifying and managing aphasia requires the co-operation and coordination of the entire stroke team, along with the daily presence of speech therapists. These considerations are crucial for patients in the stroke unit to achieve the full benefit of the management proposed in this chapter, to ultimately promote better long term functional prognosis.

INTRODUCTION

Stroke is a public health issue, representing the third leading cause of death and the first leading cause of disability in adults [1] in the western world. As the population ages, its estimated incidence of 300 to 500/100 000 is expected to increase [2]. Specialized stroke units and/or stroke teams have been created worldwide in order to provide optimized management of stroke in the hyper acute and acute stages. Recent randomized controlled trials (RCT) have proven the efficiency of specialized stroke units in reducing morbidity and mortality, and in facilitating rapid recuperation after stroke [3-6]. Aphasia is a frequent symptom of acute stroke, and a major source of disability. It incurs increased cost of care [7] and has negative economic repercussions, such as decreased return to work [8, 9]. However, early intense and sustained management of aphasia in stroke units remains controversial.

We share herein our experience of the early identification and treatment of aphasia after stroke, based primarily on a neurolinguistic framework.

We further describe existing protocols and discuss the expected benefits of early management. Optimal standardization of aphasia management can be achieved in stroke units with collaboration among physicians, nurses and speech therapists, resulting in improved outcomes after stroke. Moreover, clinically-driven research in aphasia in the acute setting is feasible and essential to improving recovery and rehabilitation outcomes.

1. IMPAIRMENTS IN THE ACUTE PHASE OF STROKE: GENERALITIES

Survivors of stroke often experience multiple co-occurring impairments, such as hemiplegia [10, 11] dysphagia [12, 13], incontinence [14, 15] depression [16], cognitive changes [17, 18], dysarthria [19, 20] and/or language impairment [21, 22]. Second to hemiparesis, dysphagia, dysarthria, and language impairment are the most frequent [20]. The incidence of dysphagia approximates 55% in the acute stage [12, 13].

Dysarthria and language impairment are almost as frequent in the acute phase of stroke, occurring in approximatively one-third of all stroke patients. Nonetheless, these impairments are probably underestimated, particularly in the hyper acute stage, given the lack of standardized assessments and the potential for rapid recovery [21, 23-25]. Dysarthria may occur as isolated speech impairment or with concomitant aphasia. Studies have reported dysarthria to range from 8 [26] to 42% [19] and aphasia to range from 15 [24] to 41% [12] following stroke.

Inclusion of different stroke etiologies, first versus recurrent stroke patients and different methodologies likely contributes to variations in reported frequencies of language impairment.

1.1. Definitions

Stroke is usually defined as a sudden onset of signs of focal disturbance of cerebral function lasting over 24 hours [27]. Language impairment literature can relate to ischemic, intracerebral hemorrhage (ICH) or subarachnoid hemorrhage (SAH) stroke etiologies.

Among stroke subtypes, ischemic etiology is the most frequent cause of stroke, followed by ICH and then SAH [28-30]. While there is typically an abrupt onset of neurological deficit after ischemic stroke, a progressive evolution, often with considerable tissue displacement [31], can also exist after ICH [26]. In addition, there is as much as a 10 fold higher frequency of decreased level of consciousness after ICH compared to ischemic stroke [26]. Consequently, aphasia can be identified very early after ischemic stroke, while patients with ICH may require ongoing monitoring for adequate identification of its presence. After ischemic stroke, some patients may fully recover from aphasia within days of stroke onset [24], thereby warranting careful monitoring for early recovery. Aphasia and other focal neurological deficits are not generally expected to occur after SAH, except occasionally as transient signs of vasospasm [30], or after aneurysm clipping [32].

Aphasia or language impairment is defined as an acquired impairment, characterized by anomia [33] and/or other deficits in expressive or receptive language, evidenced in any modality: speaking, listening, reading, or writing [34]. We use a neurolinguistic framework to describe brain behavior relationships in the identification and management of language impairment after stroke. (Figure 1)

Figure 1. Decision-making tree in aphasic patients.

1.2. Incidence, Predictors and Phenotypes of Language Impairment

Aphasia results from injury to the dominant hemisphere, which involves the left hemisphere in right-handed patients and in 70% of left-handed patients [35, 36].

CNS= Canadian Neurological Scale.; ICH=Intracerebral Haemorrhage; ISCH=Ischemic Etiology; SAH=Subarachnoid Haemorrhage

SLT=Speech Language Therapist; * first ever stroke.; (a)proportion of SAH higher than that of ICH.; (b)TIA included in ischemic category.(c)35% incidence documented at discharge, compared to 30% very early after stroke;(d)included ISCH, ICH, and undetermined etiology;(e)Excluded cerebral trauma as cause of ICH;(f)Used a cueed word finding task; combined results for those with hypothermia and those with normothermia; (g)Only included patients with good premorbid activities of daily living; (h)Geriatric ward sample of older patients.

The neural network subserving language function is increasingly recognized to be a large and complex system involving regions throughout the cerebral hemisphere. The language network comprises areas of the perisylvian cortex, including the classical language areas of Broca and Wernicke: Broca's area or Brodmann's area 44 in the posterior inferior frontal gyrus innervates adjacent motor neurons subserving the mouth and larynx, and controls the output of spoken language; Wernicke's area or Brodmann's area 22, comprising the posterior two-thirds of the superior temporal gyrus, receives information from the auditory cortex and accesses a network of cortical associations to assign word meanings; the angular gyrus in the inferior parietal lobule is adjacent to visual receptive areas and subserves the perception of written language, as well as other language processing functions. Additional regions have a significant contribution to language function: the insula, several frontal and temporal lobe regions and vast regions of the temporal, occipital, and parietal cortex, as well as subcortical nuclei. [37-42]

The incidence of aphasia may differ according to stroke etiology (see table 1). Some studies have documented aphasia in unselected stroke samples, involving all three etiologies: ischemic, ICH and SAH, with frequencies ranging between 21% [43] and 35% [44]. Samples that considered only first-ever stroke for all three etiologies have reported frequencies ranging from 17 [45] to 30% [46]. When SAH was excluded, studies have reported frequencies ranging from 23 [43] to 41% [12]. To our knowledge, only two studies have included both types of hemorrhagic stroke, reporting a combined frequency of 9% [43] and 20% [47]. After isolated ICH, the reported frequency of aphasia ranges from 15 [48] to 36% [12]. Two studies have reported aphasia frequencies of 3 [12] and 12% [31] after SAH. Documents of the frequency of aphasia after ischemic stroke range from 15 [24] to 40% [12], with frequencies ranging from 23 [20] to 39% [37] after first ischemic stroke. The presence of language impairment is preferentially associated with previous stroke [12], increasing age [12, 21, 22, 41, 42] female gender [42], stroke severity [24], atrial fibrillation [21, 22, 49, 50], cardio-embolic etiology [51]. Published reports differ concerning the frequency of phenotypes of aphasia after stroke and there is a paucity of literature describing the clinico-radiological correlation. Croquelois and Bogousslavsky recently studied 1541 patients with aphasia in the early stages of stroke (ie within the 24 hours following onset), classifying them according to aphasic patterns, where 38% presented with expressive-receptive aphasia, 37% with expressive aphasia and 25% with receptive aphasia [52] (see figure 2). In same setting, Kumral and his colleagues described a series of 454 patients with acute aphasia in the first four weeks after stroke, identifying receptive-expressive aphasia in 60%, expressive aphasia in 22%, and receptive aphasia in 14% [30]. Two studies have described more specific phenotypes in series of consecutively admitted patients with aphasia [23, 25] (see figure 2), where one demonstrated the highest frequency for expressive-receptive aphasia [23] and the other for expressive aphasia [25]. In both studies, receptive aphasia types were least frequent [23, 25]. Two additional studies have reported subtypes of aphasia in acute stroke patients following ischemic stroke and ICH, excluding SAH [43, 53]. In one of these two studies, expressive-receptive aphasia predominated [43] at 40%, while receptive aphasia was most frequent in the other [53] at 65%.

Mixed Etiologies

Isolated Etiologies – Ischemic Stroke

Isolated Etiologies – Intracerebral Hemorrhage

Figure 2. Classification of aphasia subtypes according to stroke etiologies by study. Total percentages may not equal one hundred, due to rounding to the nearest percent.

The small sample size in the latter study may account for this variation [53], when compared to the larger studies. Three studies have considered aphasia classifications after isolated etiologies. Two documented aphasia after ischemic etiology [24, 43], demonstrating that expressive-receptive aphasia predominated, with frequencies of 41% [43] and 56% [24], followed by expressive aphasia with frequencies of 27% [43] and 29% [24]. Receptive aphasia was least frequent at 14% in both studies.

Hier and his colleagues also documented aphasia subtypes after intracerebral hemorrhage, demonstrating the highest frequency for receptive-expressive aphasia at 31%, followed by expressive aphasia at 27% and then receptive aphasia at 14% [43].

Discrepancies in these results are probably due to differences between the sensitivity and specificity of tools versus bedside clinical evaluation and to the timing of evaluation, as aphasia can improve rapidly shortly after the onset of stroke. To illustrate, a study involving 130 acute ischemic stroke patients with aphasia demonstrated improvement of aphasia in 46% and resolution in 21% within the first 10 days following stroke onset [24]. In addition to reporting aphasia based on subtypes in these studies, some authors noted numerous unclassifiable aphasias (25%) [23, 43] or subcortical aphasias [23]. These unclassifiable aphasias may be comprised of patients with co-occurring subtypes or they may result from the method of determining subtypes, where certain patients do not fit the study's definition of each subtype. Also, diaschisis and "penumbra phenomenon", resulting in hypoperfusion to anatomical regions associated with aphasia, are possible explanations for rapid improvement, subcortical aphasia [23] or for evolution from nonfluent to fluent aphasia [25].

1.3. Prognosis

In spite of the potential for rapid improvement, language impairment usually still affects 50% of initially aphasic patients 18 months after stroke [25, 53], thereby contributing to altered quality of life beyond the aphasia itself [45]. Primary consequences may include symptoms of depression, difficulty to participating in rehabilitation, difficulty understanding therapists', social draw-back and decreased frequency of professional activities [54-56].

It is difficult to predict the outcome of aphasia, even if aphasia after hemorrhagic stroke has a better prognosis than after cerebral infarctions [57]. To the present day, only initial stroke severity (according to NIHSS) and the initial severity of aphasia have been shown to predict importance of aphasia recovery after acute ischemic stroke [24, 25]. In a recent study, Maas conclude that advanced age, the presence of hypodense regions, a history of previous stroke, and sedentary activity level significantly predicted a diminished likelihood of language improvement at discharge. At 6 months of follow-up, only the prestroke mRS significantly impacted likelihood of improvement [58].

2. TOOLS FOR LANGUAGE ASSESSMENT

2.1. Available Tools

Early detection of aphasia after stroke may improve rehabilitation by taking advantage of the synergy between intensive speech therapy and early neural reorganization [59-61]. Tools

capable of detecting aphasia and evaluating its severity during the acute phase of stroke might help to improve early rehabilitation and to predict outcome [62]. Standard aphasia rating scales such as the Western Aphasia Battery, the Boston Diagnostic Aphasia Evaluation (BDAE), and the Boston Naming Test are not appropriate for use during the acute phase of stroke [61, 63-65]. In particular, these gold standard test batteries take too long to complete and must be administered by speech and language therapists [63-65]. Global stroke rating scales such as the National Institutes of Health Stroke Scale and the Scandinavian Stroke Scale include language items and have been developed for use in acute settings [66-71], but they do not reliably detect aphasia [62]. Several attempts have been made to develop and validate brief aphasia screening scales suitable for patients with acute stroke [72-79], but all have inherent structural limitations, including [61]: (1) inclusion of written language subtests, the results of which are influenced by hemiplegia and illiteracy [59, 73-76, 79]; (2) use of complex visual material inappropriate for stroke patients with neuro-visual deficits [73, 74], (3) inclusion of subtests that are markedly influenced by attention/executive dysfunction [73, 74]; (4) excessively lengthy administration [76]; (5) difficulties with administration or scoring [59, 72, 76, 79]; and (6) IQ dependency [75]. Some of these scales also have poor sensitivity for the detection of aphasia and provide a little information regarding measures of validity and reliability [59, 76].

2.2. A Novel Tool: LAST, the Language Screening Test

Early and precise diagnosis of aphasia is necessary and justified for informed decision making, such as the use of thrombolysis and the implementation of early and individually-tailored rehabilitation. Evaluation may help to localize lesion site, prior to magnetic resonance imaging [80]. A quantitative tool is needed to document the risk or presence of aphasia and to quantify repeat evaluations. Such a tool would also permit description of aphasic patterns according to lesion localization, such as transcortical aphasia following acute border-zone infarcts [81, 82]. A recent study investigated the correlation between language tasks and brain lesions, concluding that word repetition, sentence repetition and naming best-predicted lesions in the left hemisphere lesion [83]. Counting and comprehension were also impaired in patients with brain injuries [83].

We recently developed and validated a brief language screening scale in French, the Language Screening Test (LAST) [84], to screen for risk of aphasia and to facilitate timely assessment of patients after acute stroke. We validated and documented reliability for two versions of the tool in an unselected sample of chronic and acute stroke patients, excluding SAH. The scale consists of 5 subtests: picture naming (items selected based on lexical familiarity and image evoking value), repetition (of a word and a sentence), automatic sequence (counting from 1 to 10), picture recognition (including semantic, visual and phonemic foils) and auditory commands (including 1 simple and 2 complex instructions). These subtests were chosen for their high correlation with left hemisphere lesions. Two parallel and equivalent versions of LAST (a and b) were developed to avoid a re-test effect. Each item is scored as 1 if correct and 0 if incorrect or inappropriate; The total scores range from 0 to 15, with a cut-off at 14 for the diagnosis of aphasia, as compared to the BDAE. The test is administered on a letter-sized sheet of paper (one side for the expressive index and one side for the receptive index). Administration requires fewer than three minutes. The simplicity

of LAST makes it suitable for bedside administration by any health professional. The LAST is useful as a rapid and reliable screen for aphasia, with proven specificity. Given the existence of two parallel versions, a second quantification of aphasia is possible during a follow-up period.

3. RECOVERY

Speech and language therapy is assumed to be beneficial; A recent Cochrane review (2010) reported some indications of the effectiveness of SLT for people with aphasia following stroke [85]. Moreover, the authors documented results favouring intensive SLT over conventional SLT. However, there was insufficient evidence in this review to establish the effectiveness of one SLT approach over another [85].

Neural processes underlying recovery remain unknown [86]. Different factors may play a role, such as age, stroke size and location, premorbid level of education, and environmental support [63]. It has been documented that hemorrhagic strokes evolve better than ischemic strokes [57]. However, the only predictive factor of speech and language recovery following cerebral infarctions is the initial severity of stroke [24, 25]. One study postulated that, as with motor recovery, improvement from aphasia is directly correlated with the initial deficiency, with an estimated recovery of 70% at 90 days post stroke onset [87]. Aphasia usually results from lesions affecting the left hemisphere in right-handed patients as well as in the majority of left-handed patients [35, 36]. Cerebral plasticity and changes in neural organization interfere with the restoration of language function [88, 89]. This is due to post-stroke compensation in the undamaged language areas, perilesional tissue and homologue right language areas [90]. In the setting of a very focal lesion, perilesional areas participate in recovery at the acute phase and during rehabilitation. Two different mechanisms are supposed: transient hypoperfusion of these territories (“penumbra”) and early neuronal reorganization with up regulation of these areas [91]. In larger lesions, language recovery could implicate the right hemisphere, as demonstrated in functional imaging and neurophysiologic studies [92-94]. Homologous right-sided regions that could be implicated in the process of language recovery are the superior temporal lobe (auditory control), the inferior frontal gyrus, pre-motor areas (planning of motor actions and nonlinguistic perception of language) and the motor cortex (execution of verbal motor actions) [86, 95, 96]. A recent study reports the extraordinary case of a man who benefited from a pre and post stroke functional MRI (fMRI): the patient presented with a Broca’s aphasia after a large ischemic infarction within the territory of the left middle cerebral artery, with almost complete recovery [96]. The fMRI shows a perilesional reorganization but no significant recruitment of the right hemisphere one year after stroke [96]. A second functional MRI study reported the dynamics of language reorganization in 14 stroke patients describing activation of perilesional areas initially (as explored at day 2) [90]. Subsequent areas of reorganization included the right homologue of Broca’s area in the sub acute period (day 12 after stroke) and later the reactivation of the left language areas in the chronic phase (explored one year after onset of symptoms) [90]. These findings should be taken in account when planning rehabilitation.

4. REHABILITATION

Speech and language therapy (SLT) aims at improving communication using verbal or nonverbal treatment modalities. Recent guidelines recommend speech therapy for patients with aphasia following stroke in spite of contradictory results from a few previous studies [85, 97, 98]. This heterogeneity could result from unsuitable tools, large heterogeneous cohorts, initiation of intensive therapy at differing time periods following stroke [99] or different rehabilitation techniques [98, 100].

Functional imaging and behavioral studies have shown that SLT can modulate neural plasticity [101]. Because inappropriate rehabilitation may interfere with reorganization of language, it should be implemented according to the aphasia classification. Therefore, semantic phonological, and/or morphosyntactic therapies should be proposed according to the initial language impairment [102, 103]. In our center, different methods of SLT are performed according to each patient's needs and type of aphasia. We suggest that therapy should be implemented on a daily basis as early after stroke onset as possible. In particular, the specific contributions of the right hemisphere, such as prosodic and rhythmic properties of language, should be targeted in therapy to favor activation of contralateral language areas [104]. Early SLT in nonverbal patients or patients with severely reduced verbal output is important in order to avoid stereotypes. In accordance with one hypothesis on the dynamics of language recovery, and to capitalize on the potential role of the right hemisphere, we practice early SLT using melodic intonation therapy (MIT) [92]. We have proposed an auditory stimulation program, using a daily music listening program in our unit (one hour of music with French lyrics for our francophone population), derived from recently reported benefits [104]. Patients are encouraged to listen to music with lyrics and to actively sing along. A recent study with clinician blinding has sought to determine the immediate effects of introducing MIT early after stroke onset in patients with Broca's aphasia [105]. The treatment group showed a significant improvement compared to the control group, supporting the benefit of using this therapy method after acute stroke [105].

Although some have argued that early speech therapy is not feasible or necessary, we contend that it is indeed feasible and paramount to optimizing recovery. Second to promoting language recovery, initiation of therapy may reassure patients and help educate caregivers. As part of the therapeutic initiative, caregivers are provided advice for supportive communication [106] and to aid in eliciting compensatory strategies from the patient. Early therapy also facilitates better communication in patient care regarding medical explanations, instructions, and interactions with other therapists and the medical team.

Contribution from the entire medical and paramedical team is essential in the treatment of aphasia. In our stroke unit, therapeutic information is discussed with nursing staff, because their frequent patient interactions are crucial for progression toward rehabilitation goals. Their numerous daily interventions with patients may play a role in increasing the intensity and functionality of speech and language objectives. Providing adequate information about aphasia to front-line health professionals and families is essential to avoid ambiguous interactions. This will promote clear explanations conducive to the reception capabilities of patients. Similar educational information and explanations are necessary for both families and caregivers to avoid misconceptions. For example, some relatives may think that a patient has incurred hearing loss, amnesia, cognitive decline or dementia, psychiatric disorders or that the

patient lacks physical sensation or emotion. Unfortunately, aphasia is not well understood, and educating family members and caregivers is essential to facilitate faster and more efficient recovery on the part of patients. Families and caregivers need to be well informed about the diagnosis and potential prognosis of the aphasia. As with front-line health care workers, other health professionals, such as physiotherapists or occupational therapists are inherently implicated in language rehabilitation in the acute phase. Their actions should be verbalized in an accessible formulation, with clear articulation, and with sufficient confirmation that the patient understands the instructions. In patients who are nonverbal or who have extremely limited verbal output, compensatory strategies such as the use of pictures, gestural communication, and letter require explanation to families and caregivers to prevent communication breakdown. Associated impairments, such as anosognosia after posteriorly localized aphasia and depression after anteriorly localized aphasia require additional considerations and caregiver education from the stroke team.

5. PERSPECTIVES

Effectiveness of SLT has been shown in different studies, and tools are now available to assess aphasia in acute stroke. Randomized controlled trials are still needed to indicate the best approach to delivering speech and language therapy. This will inform indications for the optimal approach, frequency, and duration of allocation and format of SLT for specific patient groups. Fortunately, recent randomized controlled studies have been conducted in the acute stage with a particular consideration of methods of speech therapy [103, 107]. Controversy from potentially contradictory results arose from methodological differences such as group size, randomization methods, and type, timing (early vs. delayed) and frequency of therapy (intensive vs. conventional) [85, 98, 108]. Intensive SLT, of any type, has been shown to be beneficial according to some authors [103]. Others consider that “intensive” and “early” SLT should be undertaken to promote early neuronal re-organization [59-61, 103].

Considering different therapy types by SLTs, a recent RCT investigated the effect of “Language enrichment therapy” [107], starting at day 2 post stroke and continuing to day 21. The control group received no SLT for at least the first 21 days post stroke. At day 21, 58% of the treatment group achieved a higher score on the aphasia test battery, while 35% achieved higher scores in the control group. However, the treatment group did not maintain gains in verbal communication six months following stroke. A more recent pilot RCT evaluated daily SLT according to patient classifications of aphasia, involving linguistically driven therapeutic tasks [103]. They compared patient tailored therapy with usual care and found that patients in the treatment group had significantly higher scores on the aphasia quotient and on a functional communication measure than the usual care group. Additional RCTs are still needed to better determine the optimal type, timing and intensity of speech language therapy in the setting of acute stroke.

The validation and availability of the LAST and the recent demonstration of the feasibility of conducting RCTs in the very early stages of stroke provide the impetus for designing future randomized studies that take type, timing and intensity of SLT into account after acute stroke. In addition, use of a validated language scale, such as the LAST, in

randomized trials or consecutive cohorts, could further promote research correlating acute clinical signs of aphasia with MRI, by which the efficacy of therapy for aphasia subtypes could be documented.

CONCLUSION

The early detection of aphasia after stroke is essential for reliable diagnosis in order to optimize rehabilitation. Available recent tools now allow for rapid and precise assessment of aphasia. Standard care protocols and teamwork promote best practice in the use of these tools, rendering them more efficient and effective. The implementation of such protocols involves the cooperation and coordination of both medical and paramedical personnel and the daily presence of speech therapists in stroke units. In particular, we recommend this daily presence for patients with aphasia, so that they may derive maximum benefit and the advantages of units that provide this type of standard care. Consequently, we expect that the long-term functional prognosis of these patients with aphasia will improve. Moreover, future randomized trials are essential to develop specific interventions for and to optimize SLT support.

Chapter 94

A NEW CLASSIFICATION OF APHASIAS

Alfredo Ardila*

Department of Communication Sciences and Disorders
Florida International University, Miami, FL, US

ABSTRACT

In this chapter it is emphasized that there are only two fundamental forms of aphasia, which are linked to impairments in the lexical/semantic and grammatical systems of language (Wernicke-type aphasia and Broca-type aphasia, respectively). Other aphasic syndromes do not really impair language knowledge per se, but rather either some peripheral mechanisms required to produce language (conduction aphasia and aphasia of the supplementary motor area), or the executive control of the language (extra-Sylvian or transcortical motor aphasia). A new classification of aphasic syndromes is suggested. In this proposed classification a distinction is established between primary (or “central”) aphasias (Wernicke’s aphasia—three subtypes—and Broca’s aphasia); secondary (or “peripheral”) aphasias (conduction aphasia and supplementary motor area aphasia); and dysexecutive aphasia.

INTRODUCTION

Aphasia represents the most studied cognitive syndrome associated with brain pathology. As a matter of fact, the analysis of aphasia represents the initial question and departing point in modern cognitive neuroscience. Understanding aphasia is consequently most crucial in our interpretations about brain organization of cognition.

Diverse aphasia classifications have been proposed since Broca’s first description of a language disturbance associated with brain pathology (Broca, 1863). There are, however, two most influential aphasia classifications, that have significantly guided the area during the last decades: the Boston Group classification (Geschwind, Benson, Alexander, Goodglass,

* Corresponding Author Email: ardilla@fiu.edu (11200 SW 8th Street, AHC3-431B, Florida International University, Miami, Florida 33199).

Kaplan, and others); and Luria’s aphasia interpretation. The first one has been particularly influential in the US and western European countries; the second one has been mostly used in eastern European countries and Latin America.

Boston Group classification represents a further development of Wernicke’s ideas about brain organization of language, and includes two basic distinctions: (1) aphasias can be fluent or non-fluent; and (2) aphasias can be cortical, subcortical, or transcortical (e.g., Albert, Goodglass, Helm, Rubers, & Alexander, 1981; Alexander & Benson, 1991; Benson, 1979; Benson & Geschwind, 1971, 1985; Geschwind, 1965; Goodglass, 1993; Goodglass & Kaplan, 1972). Conduction aphasia (initially proposed by Wernicke in 1874 and described by Lichtheim in 1885) was introduced to account for the language repetition impairments frequently found in left parietal (or insular) damage.

Luria (1966, 1970, 1974, 1976, 1980) proposed, initially six, but later seven aphasia subtypes: motor efferent or kinetic, motor afferent or kinesthetic, acoustic-agnosic, acoustic-amnesic, amnesic, semantic, and dynamic). Luria assumed that in each aphasia subtype there is a particular language processing defect. In Luria’s approach, aphasia subtypes and names refer to the specific level of language that is impaired.

Benson and Ardila (1996) attempted to integrate both points of view and proposed a classification based on two different anatomical criteria: (1) aphasia can be pre-Rolandic (anterior, non-fluent) or post-Rolandic (posterior, fluent); and (2) aphasia can be associated with pathology in the peri- Sylvian language area (peri-Sylvian aphasias); or aphasia is due to damage beyond this area (extra-Sylvian). Subtypes were introduced for some aphasia syndromes. Aphasias were also regarded as anatomical syndromes (Table 1). This classification is currently used by different authors (e.g., Basso, 2003).

Table 1. Two major parameters are used in aphasia classification:
(a) Aphasia can be pre-Rolandic or post-Rolandic; (b) Aphasia can be peri-Sylvian or extra-Sylvian. Clinical syndromes are related to anatomical syndromes

	Pre-Rolandic	Post-Rolandic
Peri-Sylvian	Broca's Type I (triangular syndrome)	Conduction (parietal-insular syndrome)
	Broca's Type II (triangular-opercular-syndrome)	Wernicke's Type I (posterior insular-temporal isthmus syndrome)
		Wernicke's Type II (superior and middle temporal gyrus syndrome)
Extra-Sylvian	Extra-Sylvian Motor Type I (left prefrontal dorsolateral syndrome)	Extra-Sylvian Sensory Type I (temporal-occipital syndrome)
	Extra-Sylvian Motor Type II (supplementary motor area syndrome)	Extra-Sylvian Sensory Type II (parieto-occipital angular syndrome)

According to Benson & Ardila, 1996.

During the last decades significant advances in the understanding of brain organization of language has been obtained. Contemporary neuroimaging techniques, such as fMRI (e.g., Meinzer, Harnish, Conway & Crosson, 2011; Zahn et al., 2000), PET (Cao, George, Ewing, Vikingstad & Johnson, 1998) and tractography (Song et al., 2011; Yamada et al., 2007), have significantly extended our understanding of the organization of language in the brain under normal and abnormal conditions (Lee, Kannan & Hillis, 2006; Small & Burton, 2002); a significantly better understanding of the brain circuitries supporting language has been developed (e.g., Ullman, 2004); and a re-analysis of the classical language areas (Broca's and Wernicke's) has been developed (e.g., Grodzinsky & Amunts, 2006); and new scientific discoveries, such as the "mirror neurons", have changed our understanding of the functioning of the human brain, including language organization (e.g., Rizzolatti & Arbib, 1998).

In this chapter a further attempt is made to integrate these new advances; a new classification of aphasia syndromes will be proposed. This new aphasia classification was recently presented (Ardila, 2010) and has been discussed by several authors (e.g., Buckingham, 2010; Kertesz, 2010; Marshall, 2010).

THERE ARE ONLY TWO MAJOR APHASIC SYNDROMES

There is a fundamental point in the analysis of aphasia: aphasia is not one, but two different clinical syndromes, initially described by Broca in 1861 and Wernicke in 1874. These two syndromes have been named in different ways, but roughly corresponding to Wernicke-type aphasia and Broca-type aphasia (e.g., Ardila, 2010; Albert et al., 1981; Alexander & Benson, 1991; Bastian, 1898; Benson & Ardila, 1996; Freud, 1891/1973; Goldstein, 1948; Head, 1926; Hecaen, 1972; Kertesz, 1979; Lichtheim, 1885; Luria, 1976; Pick, 1931; Schuell, Jenkins, & Jimenez-Pabon, 1964; Taylor-Sarno, 1998; Wilson, 1926; see Tesak & Code, 2008, for review).

Aphasia represents a language disturbance and consequently, not only a neurologic/anatomic but also a linguistic understanding is required. Jakobson (1964; Jakobson & Halle, 1956) proposed that these two major aphasic syndromes are related to the two basic linguistic operations: selecting (language as paradigm) and sequencing (language as syntagm). Jakobson (1964) proposed that aphasia tends to involve one of two types of linguistic deficiency. A patient may lose the ability to use language in two rather different ways: the language impairment can be situated on the paradigmatic axis (similarity disorder) or the syntagmatic axis (contiguity disorder). The first one is related with the Wernicke-type aphasia, and the second one with the Broca-type aphasia.

Wernicke-Type Aphasia

In Wernicke-type aphasia the lexical repertoire tends to decrease and language-understanding difficulties are evident. Wernicke's aphasia patients may not fully discriminate the acoustic information contained in speech (Robson, Keidel, Ralph & Sage, 2012). Lexical (words) and semantic (meanings) associations become deficient. In Wernicke-type aphasia

the language defect is situated at the level of meaningful words (nouns). Phoneme and word selection are deficient, but language syntax (contiguity: sequencing elements) is well preserved and even overused (paragrammatism in Wernicke aphasia). Wernicke-type aphasia represents the clinical syndrome characterized by impairments in the selection process (paradigmatic axis defect).

Patients with Wernicke aphasia have problems in recalling the words (memory of the words) and also in associating the words with specific meanings: the semantics of the words can be abnormal. This means that at least three different deficits underlie Wernicke-type aphasia: (1) phoneme discrimination impairments (auditory verbal agnosia); (2) verbal memory impairments; and finally (3) lexical/semantic association deficits. Robson, Sage and Ralph (2012) emphasized that deficits responsible for the comprehension defects in Wernicke aphasia are diverse, including acoustic-phonological defects, and semantic deficits.

Figure 1 presents in a summarized form the model proposed by Ardila (1993) to account for language recognition. It is assumed that there are three different levels of language understanding (phoneme recognition, lexical recognition, and semantic recognition). These three language understanding levels can be impaired in cases of Wernicke-type of aphasia. In consequence, there are three different subtypes of Wernicke aphasia: Acoustic-agnosic type (associated with phoneme recognition defects), acoustic amnesic type (associated with lexical recognition defects), and amnesic, nominal or traditionally called transcortical (extrasyllvian) sensory aphasia (associated with semantic recognition defects).

Adapted from Ardila, 1993.

Figure 1. Three levels of language recognition potentially impaired in Wernicke-type aphasia can be distinguished: phonemic (categorical perception level I), lexical (categorical perception level II), and semantic (categorical perception level III). Three different sub-syndromes can be found: phonemic discrimination defects (acoustic-agnosic or Wernicke's aphasia type I), verbal-acoustic memory defects (acoustic-amnesic or Wernicke's aphasia type II), and semantic association defects (amnesic, nominal or extra-Sylvian sensory aphasia).

Broca-Type Aphasia

In Broca-type of aphasia, language defects are quite different; while the lexical/semantic dimension of the language is preserved, grammar is seriously impaired. Language is scarce,

nonfluent, and poorly articulated, but language understanding is relatively well preserved. That means, the selection process (paradigmatic axis) is normal. According to Jakobson (1964) in Broca-type aphasia the syntagmatic axis of language is impaired. There is a defect in language sequencing (morphosyntax). Indeed, in Broca's aphasia two different distinguishing characteristics can be observed, one at the motor level and the other at the purely language level: (1) there is on one hand a motor component (lack of fluency, disintegration of the speech kinetic melodies, verbal-articulatory impairments, etc., that is usually referred as apraxia of speech); and (2) on the other hand, there is a reduction in the grammar, usually referred as agrammatism (e.g., Benson & Ardila, 1996; Berndt & Caramazza, 1980; Goodglass, 1993; Kertesz, 1985; Luria, 1976). Interestingly, a large part of the fronto-parieto-temporal cortex has been observed to be involved with syntactic-morphological functions (Bhatnagar, Mandybur, Buckingham, & Andy, 2000). Apraxia of speech has been observed specifically associated with damage in the left precentral gyrus of the insula (Dronkers, 1996; but see Hillis et al., 2004). It should be noted that not all of apraxia of speech is indeed a contiguity disorder; there are many phonetic-level errors in apraxia of speech that have more to do with segmental distortions. If both impairments (apraxia of speech and agrammatism) are simultaneously observed (i.e., they are very highly correlated), it can be assumed they are just two different manifestations of a single underlying defect. It is not easy to understand which one could be the single factor responsible for these two clinical manifestations, but it may be kind of "inability to sequence expressive elements". Broca's area, most likely, is not specialized in producing language, but in certain neural activity that can support not only skilled movements required for speech, but also morphosyntax. It has been observed that indeed language networks supporting grammar and fluency are overlapped in the brain (Borovsky, Saygin, Bates, & Dronkers, 2007).

HOW TO INTERPRET OTHER APHASIC DISTURBANCES?

Frequently it has been assumed that three major (perisylvian) aphasic syndromes can be distinguished: frontal Broca aphasia, temporal Wernicke aphasia, and parietal conduction aphasia (e.g., Benson, 1979; Goodglass, 1993). These are the three aphasia disorders associated with damage in the so-called "brain language area"; a concept introduced by Dejerine (1914), roughly corresponding to the perisylvian area of the left hemisphere, and including partially the frontal, temporal and parietal lobes of the left hemisphere.

In addition to Broca, Wernicke and conduction aphasia, aphasia classifications generally include a diversity of additional language disturbances, such as transcortical (extra-Sylvian) aphasia, and anomic aphasia (e.g., Alexander & Benson, 1991; Benson & Geschwind, 1971; Hecaen & Albert, 1978; Kertesz, 1979; Lecours, Lhermitte, & Bryans, 1983; Luria, 1966). However, some aphasic syndromes can eventually be considered as variants of the Broca and Wernicke aphasias. For instance, as mentioned above, amnesic or anomic or nominal aphasia (usually due to damage in the vicinity of BA 37) (Head, 1926; Hecaen & Albert, 1978; Luria, 1976), as well as transcortical sensory aphasia can be interpreted as subtypes of Wernicke aphasia in which the semantic associations of the words are significantly impaired (see Figure 1).

No question, the major difficulty in interpreting these additional syndromes refers to conduction aphasia, considering that conduction aphasia is frequently regarded as one out the three major aphasia syndromes (in addition to Broca aphasia and Wernicke aphasia).

Conduction Aphasia

A crucial question is, how conduction aphasia—a well recognized and extensively studied aphasic syndrome (e.g., Benson & Ardila, 1994; Damasio & Damasio, 1980; Goldstein, 1948; Kohn, 1992) — can be interpreted?

The most frequent, and classic, explanation of conduction aphasia is as a disconnection syndrome (e.g., Damasio & Damasio 1980; Geschwind 1965; Wernicke 1874), usually due to a lesion affecting the arcuate fasciculus (Yamada et al., 2007) and sporadically an indirect pathway passing through the inferior parietal cortex (Catani, Jones, & Ffytche, 2005). This is the usually explanation, sometimes referred as the Wernicke-Geschwind disconnection model of conduction aphasia. Alternatively, conduction aphasia has also been interpreted as a segmentary ideomotor apraxia (e.g., Ardila & Rosselli., 1990; Brown, 1972, 1975; Luria 1976, 1980). According to this second interpretation, conduction aphasia could be regarded as a verbal apraxia, an ideomotor apraxia impairing the movements required for speaking, or simply as a kinesthetic apraxia of speech. Luria (1976) suggested that paraphasias in conduction aphasia (Luria's kinesthetic motor or afferent motor aphasia) are indeed articulatory-based deviations (articulatory literal paraphasias), not really phonological disturbances. Paraphasias in conduction aphasia are due mainly to phoneme substitutions and phoneme deletions; they result basically in switches in phoneme manner and place of articulation (Ardila, 1992). Similarities between errors in ideomotor apraxia and conduction aphasia language deficits have been suggested.

According to Benson, Sheretaman, Bouchard, Segarra, Price, and Geschwind (1973) conduction aphasia has three fundamental and five secondary characteristics; so-called secondary characteristics are frequently but not necessarily found in conduction aphasia. The three basic characteristics are: (1) fluent conversational language; (2) comprehension almost normal; and (3) significant impairments in repetition. Secondary characteristics include: (1) impairments in naming; (2) reading impairments; (3) variable writing difficulties (apraxic agraphia); (4) ideomotor apraxia; and (5) additional neurological impairments. Bartha and Benke (2003) report that conduction aphasia patients present as relatively homogenic in their aphasic manifestations: severe impairment of repetition and fluent expressive language functions with frequent phonemic paraphasias, repetitive self-corrections, word-finding difficulties, and paraphrasing. Repetitive self-corrections frequently result in so-called *conduit d'approche*. Language comprehension (auditory and reading) is only mildly impaired.

Benson et al.'s. (1973) description of conduction aphasia clearly recognizes that spontaneous language production and language understanding are significantly preserved. In consequence, some mechanisms required for correct language repetition are impaired, but the knowledge of language itself (phonology, lexicon, semantics, and grammar) is not impaired. The critical question is: Should conduction aphasia be interpreted as a primary aphasic syndrome? Indeed, language repetition impairments can be observed in different aphasia syndromes and language repetition has also been interpreted as a right hemisphere ability (Berthier et al., 1991).

The distinction between “aphasias with repetition impairments” vs “aphasias without repetition impairments” is indeed a general and crude distinction. It has been proposed that different aphasia groups (including the so-called transcortical aphasias) may present language repetition errors; but depending on the specific repetition task, errors may be evident or may be unnoticed in a particular aphasic group (Ardila & Rosselli, 1992). Different mechanisms underlying repetition deficits have been proposed: limitation of auditory-verbal short-term memory, difficulties at the level of phonological production, impairments in phoneme recognition, and semantic and syntactic comprehension defects. Simply speaking, different deficits can be responsible for the repetition defects found in aphasia. Furthermore, difficulties in language repetition depend on the specific repetition task (short words, long sentences, meaningful, meaningless, etc).

Conduction aphasia is, consequently, not a primary form of aphasia, but rather a secondary (or “peripheral”) defect in language indirectly affecting a specific language ability (i.e., the ability to repeat). Language itself is not impaired, but rather it represents an impaired ability to reproduce aloud the auditory information that is heard. Of course, this is an important skill used not only to develop language but also to use it correctly. Interpreting conduction aphasia as a secondary (or “peripheral”) defect in language (rather than a primary or central form of aphasia) does not in any way decrease the importance of repetition in language.

In brief, it can be argued that conduction aphasia can be interpreted as a “secondary” (or “peripheral”) language disturbance, rather than a primary (or “central”) form of aphasia. Language knowledge is well preserved in conduction aphasia, but there is a limitation in a particular language function, i.e., repetition. Obviously, if some animals can repeat, that means that language repetition cannot be considered as a primary linguistic ability.

Interestingly, Jakobson (1964) suggested a similar distinction when proposing that in aphasia language could be either “disintegrated” or “limited” (disintegration vs limitation in aphasia). Obviously language is disintegrated only in Wernicke and Broca aphasia. In other forms of aphasia, including conduction aphasia, language is limited, not disintegrated.

Transcortical (Extra-Sylvian) Motor Aphasia

Patients with left convexital prefrontal damage usually present a lack of verbal initiative and a significant limitation in the active use of the language, referred as transcortical (extra-Sylvian) or dynamic aphasia. Extra-Sylvian (transcortical) motor aphasia could be interpreted as an executive function defect specifically affecting language use. The ability to actively and appropriately generate language appears impaired while the phonology, lexicon, semantics, and grammar are preserved.

Should the ability to correctly generate language be regarded as a linguistic ability (i.e., cognitive ability)? Or rather, should it be considered as an executive function ability (i.e., metacognitive ability)? It does not seem difficult to argue that the ability to correctly organize language sequences can be regarded as an executive function and as a metacognitive ability rather than a purely linguistic ability. Some rationales to support this interpretation are: (1) It could be argued that in extra-Sylvian (transcortical) motor aphasia there is a defect in verbal initiative rather than in language knowledge (Kleist, 1934). (2) Different authors (for example, Luria, 1976, 1980) have emphasized that this type of aphasia shares the general

characteristics of prefrontal (i.e., dysexecutive) syndrome but specifically with regard to verbal processes. This means, it is the prefrontal (dysexecutive) syndrome affecting the verbal processes (Gold et al., 1997). (3) Further, the impairment in extra-Sylvian (transcortical) motor aphasia does not affect language understanding, and fundamental linguistic processes are preserved (Berthier, 1999). And finally, (4) it could be argued that the prefrontal cortex does not participate in basic cognition, but rather in metacognition (e.g., Ardila & Surloff, 2011).

In consequence, extra-Sylvian (transcortical) motor aphasia does not necessarily have to be interpreted as a primary aphasic syndrome, but rather as a language disturbance due to a more general intellectual impairment (dysexecutive syndrome). Extra-Sylvian (transcortical) motor aphasia could indeed be referred to as “dysexecutive aphasia”. Some authors have previously interpreted extra-Sylvian motor aphasia in a similar way (e.g., Luria 1976, 1980). Alexander (2006) suggested that transcortical motor aphasia could be more accurately defined as an executive function disorder rather than aphasia. He proposed that the progression of clinical disorders from aphasia to discourse impairments can be interpreted as a sequence of procedural impairments from basic morpho-syntax to elaborated grammar to narrative language, correlated with a progression of the focus of the damage from posterior frontal to polar and/or lateral frontal to medial frontal.

Transcortical (Extra-Sylvian) Sensory Aphasia

Transcortical (extra-Sylvian) sensory aphasia (TSA) has been a polemic syndrome. Seemingly, the polemic is related to the way TSA is defined.

TSA has been defined in two partially different ways; (1) according to its “basic” definition, TSA is a fluent language disorder characterized by impaired auditory comprehension, with preserved repetition (Albert et al., 1981; Berthier, 1999; Goldstein, 1948; Lichtheim, 1885). Consequently, there are only three distinguishing characteristics in TSA (normal fluency, impaired auditory comprehension, and preserved repetition). In such a case, TSA presents similar deficits as in Wernicke’s aphasia, but repetition ability is spared and phoneme discrimination impairments are not found. (2) According to its “extended” definition, TSA also includes a semantic jargon (Goodglass, 1993; Kertesz, 1982; Lecours, Osborn, Travies, Rouillon, & Lavalle-Huyng, 1981). Kertesz (1985, p. 317) makes a comprehensive definition of TSA: “TSA is characterized by fluent and often irrelevant speech output, very poor comprehension and well-preserved repetition. Spontaneous speech often consists of semantic jargon that has no relationship to what is being asked of the patient”. This definition clearly recognizes that there are three basic characteristics, and sometimes jargon is found. But jargon is not a required symptom for the diagnosis of TSA. By the same token, other language impairments can also be found, such as poor naming, and preserved oral reading with impaired reading comprehension, but their presence is not essential to establish the diagnosis of TSA (Berthier, 1999).

According to Berthier (1999) the most common pattern of verbal expression is represented by the so-called “semantic” or “verbal” jargon (e.g., Lecours & Rouillon, 1976). There is an abundant language production, with reduction of meaningful words conferring the impression of emptiness. The content of the sentence is irrelevant. Furthermore, TSA patients appear unaware of their logorrhea (Lebrun, 1987). A second

pattern of spontaneous speech described by Berthier (1999) is referred to as “anomic” and is associated with an impaired access to content words. This second pattern corresponds to the TSA “basic” definition mentioned above.

Because repetition is spared, phonological processing is assumed to be preserved, at least partially, while lexical-semantic information included in the word meaning is impaired (Boatman et al., 2000). Usually, it is accepted that TSA is associated with relatively extensive posterior lesions including the temporo-parieto-occipital junction of the left hemisphere but sparing the areas around the primary auditory cortex (Berthier, 1999). Damasio (1991) observed that TSA is associated with lesions involving the temporal-occipital area (BA 37), the angular gyrus (BA 39), or the white matter underlying these regions, but sparing the primary auditory cortex (BA 41 and 42), and BA 22. Damasio suggested that the core area for TSA is the temporal-occipital area (BA 37) with variable extension to the occipital lobe and the angular gyrus. Kertesz (1982) analyzed 15 patients with TSA and proposed two different subgroups: one is more medial, inferior, and posterior and is clearly in the posterior cerebral artery territory; and the other is relatively more lateral, superior, and anterior and seems to be in a watershed area between middle cerebral and posterior cerebral arteries.

Benson and Ardila (1996), considering this variability in TSA, also distinguished two subtypes: the first one similar to Luria’s amnesic aphasia (BA 37), and the second one corresponding Luria’s semantic aphasia (BA 39). This distinction is coincidental with the neuroanatomical correlates of TSA found by Damasio (1991).

Recent reports support the assumption that TSA is usually found associated with extensive lesions of the left hemisphere (e.g., Warabi, Bandoh, Kurisaki, Nishio, & Hayashi, 2006), generally involving large portions of the temporal-parietal-occipital areas. According to Alexander, Hiltbrunner, and Fischer (1989) the critical lesion for transcortical sensory aphasia in these patients involved pathways in the posterior periventricular white matter adjacent to the posterior temporal isthmus, pathways that are most likely converging on the inferolateral temporo-occipital cortex.

TSA represents a disorder in the semantic recognition of language that may or may not be associated during the acute stage with other language impairments, specially logorrhea and jargon, depending on the extension of the lesion. But logorrhea and jargon are not required in the definition of TSA.

Supplementary Motor Area (SMA) Aphasia

This is a type of language disturbance recognized relative late in the aphasia history. Supplementary motor area (SMA) aphasia indeed is not associated with damage in the so-called “language area” of the brain. Penfield and Welch (1951) first observed arrest of speech associated with stimulation of this cortical region. Clinical characteristics of this type of aphasia were described by Rubens (1975, 1976).

Language disturbances in cases of damage of the left SMA have been characterized by, (1) an initial mutism lasting about 2–10 days; (2) later, a virtually total inability to initiate speech, (3) a nearly normal speech repetition, (4) a normal language understanding, and (5) absence of echolalia. A right leg paresis and right leg sensory loss are observed; a mild right shoulder paresis and Babinski sign are also found. Language recovery is outstanding and it is usually observed during the following few weeks or months (Ardila & Benson, 1996; Rubens,

1975, 1976). The occlusion of the left anterior cerebral artery is the most frequent etiology, but it has also been reported in cases of tumors and traumatic head injury (e.g., Ardila & Lopez, 1984).

SMA is a premotor area (medial extension of BA 6) participating in initiating, maintaining, coordinating, and planning complex sequences of movements; it receives information from the posterior parietal and frontal association areas, and projects to the primary motor cortex (Kandel, Schwartz & Jessell, 1995). SMA damage is also associated with slow reaction time (Alexander, Stuss, Picton, Shallice, & Gillingham, 2007). It has been observed that activation of the SMA precedes voluntary movement (Erdler et al., 2000); a crucial role in the motor expression of speech processing has also been postulated (Fried et al., 1991). Nonetheless, the SMA is located some distance -and indeed far away- from the classic language area postulated by Dejerine (1914) and assumed in most anatomical models of aphasia.

Neuroimaging studies in humans have demonstrated that SMA is active when performing various cognitive tasks, such as spatial working memory (Jonides et al., 1993), verbal working memory (Paulesu, Frith, & Frackowiak, 1993), arithmetic tasks (Dehaene et al., 1996; Hanakawa et al., 2002), spatial mental imagery (Mellet et al., 1996), and spatial attention (Simon et al., 2002).

Evidently, the SMA is a complex motor cortical area, not primarily a language related brain area. Its role in language seemingly refers to the motor ability to initiate and maintain voluntary speech production.

CONCLUSION

From the above analysis it is evident that the term “aphasia” has been used to refer both to primary language disturbances, affecting the language system itself (phonology, lexicon, semantics, grammar), and to other impairments not affecting the language system itself, but affecting some abilities required for using language. Aphasia is usually interpreted and understood as a disturbance in the language, not in some mechanisms required to produce and use the language.

A major distinction can be established between primary language disturbances (central aphasia, language is disintegrated), and secondary language disturbances resulting from “peripheral” impairments (secondary or “peripheral” aphasia; language is limited). In the primary aphasia the language itself is impaired. In the secondary language disturbances, some mechanism required to produce the language is altered. Sometimes language is not impaired, but the patient cannot use it appropriately because of executive control impairments (dysexecutive aphasia).

Table 2 presents a proposed interpretation and classification of aphasia syndromes. A distinction between primary aphasia (Wernicke-type and Broca-type; language is disintegrated as a paradigm --selection process--; or as a syntagm --sequencing process--) and secondary aphasia (conduction aphasia and aphasia of the supplementary motor area; language is limited in a specific aspect) is introduced; extra-Sylvian (or transcortical) motor aphasia is interpreted as a dysexecutive aphasia (the active use and executive control of the language is limited).

Table 2. A proposed new classification of aphasias. A distinction between primary aphasias (Wernicke-type and Broca-type) and secondary aphasias (conduction aphasia and aphasia of the supplementary motor area) is introduced; extra-Sylvian (or transcortical) motor aphasia is interpreted as a dysexecutive aphasia

Type	Impairment
<i>Primary (central) aphasias</i>	<i>Language system impaired</i>
Wernicke-type aphasia (fluent aphasia)	Phonological level Lexical level Semantic level
Broca-type aphasia(non-fluent aphasia)	Sequencing expressive elements at syntactic and phonetic level
<i>Secondary (peripheral) aphasias</i>	<i>Mechanisms of production impaired</i>
Conduction aphasia	Disconnection (or segmentary ideamotora verbal apraxia)
SMA aphasia	To initiate and maintain voluntary speech production
<i>Dysexecutive aphasia</i>	<i>Language executive control impaired</i>
Extra-Sylvian (transcortical) motor aphasia	Executive control of language

According to Ardila, 2010.

- linear, xvi, xix, xxiii, xxxii, xliii, 25, 99, 100, 101, 103, 104, 106, 111, 113, 115, 118, 263, 264, 267, 268, 276, 279, 280, 286, 287, 290, 305, 422, 425, 427, 475, 479, 637, 643, 696, 697, 716, 892, 971, 1080, 1141, 1201, 1293, 1344, 1368, 1416, 1426, 1453, 1465, 1467, 1475, 1476, 1480, 1486, 1586, 1596, 1638, 1699, 1700, 1701, 1702, 1704, 1706, 1711, 1714
- configurational, 1704
- rules, 1714
- linear function, 643
- linear model, 305, 971
- lingual coarticulation, 637, 645, 647, 649, 650, 656, 657, 658, 661, 662
- taxonomies, 1711
- unit, 436, 680, 706, 1302, 1310, 1316, 1415, 1420, 1428, 1467, 1469, 1470, 1694, 1701, 1703, 1704
- variation, 1533, 1534, 1537
- linguistic metaphors, 1556, 1557, 1559, 1560, 1562, 1563
- linguistic processing, xxxiii, xxxiv, 602, 603, 989, 1013, 1014, 1035, 1621, 1764, 1771
- linguistic rule, 584, 591, 1013, 1762
- linguistic task, 72, 279, 995, 1005, 1015, 1016
- linked labels, 1700, 1701, 1708
- linking, 5, 81, 123, 493, 722, 732, 797, 971, 1077, 1158, 1201, 1318, 1366, 1649, 1650, 1699, 1702, 1714, 1767, 1771
- listener, xviii, xix, 50, 157, 168, 181, 183, 186, 187, 192, 196, 207, 235, 236, 243, 464, 639, 641, 655, 660, 802, 973, 1133, 1141, 1163, 1371, 1603, 1604, 1625, 1631, 1704
- comprehension, xxii, xxxii, 38, 86, 96, 222, 245, 435, 437, 438, 439, 440, 441, 442, 443, 444, 796, 854, 886, 892, 905, 906, 1148, 1151, 1154, 1158, 1163, 1262, 1266
- listing, 204, 211, 1280
- event(s), 980, 981
- practice, 969, 971, 972, 973, 979, 980, 981, 982
- practice(s), 969, 971, 972, 973, 979, 980, 981, 982
- literal, xliv, 17, 22, 124, 125, 135, 383, 391, 428, 636, 976, 1082, 1217, 1378, 1533, 1534, 1535, 1536, 1537, 1538, 1539, 1540, 1541, 1542, 1543, 1544, 1545, 1546, 1550, 1557, 1562, 1602, 1604, 1615, 1672, 1675, 1864
- literature reviews, 345, 1694, 1720
- local, xliii, 236, 289, 322, 564, 568, 569, 651, 720, 785, 820, 828, 833, 834, 835, 914, 917, 921, 923, 929, 942, 956, 969, 972, 977, 983, 991, 1032, 1040, 1059, 1131, 1195, 1281, 1301, 1346, 1353, 1479, 1482, 1515, 1518, 1519, 1524, 1525, 1557, 1591, 1592, 1706
- localization, 993, 1006, 1730, 1848
- locus, 212, 642, 643, 659, 662, 888, 1346, 1435, 1451, 1454, 1455, 1457, 1471, 1733
- locus equations, 642, 643, 662
- logic, 336, 973, 974, 1071, 1222, 1363, 1372, 1427, 1435, 1497, 1664, 1696, 1800
- logical implication, xlv, 1693, 1696
- logical reasoning, 1721
- logically, 521, 647, 677, 806, 807, 808, 1118, 1375, 1423, 1424, 1431, 1469, 1504, 1688, 1702, 1710
- logics, 1720
- logopenic, xlix, 1709, 1712, 1716, 1717, 1718, 1719, 1803, 1821
- loneliness, 1748, 1774, 1781, 1782, 1784, 1785, 1789, 1790, 1793, 1797, 1799
- longitudinal study, 36, 44, 45, 62, 66, 78, 79, 81, 258, 418, 440, 442, 444, 447, 468, 508, 530, 618, 630, 881, 911, 1754
- longitudinally, xxxii, 437, 609, 891, 897, 1700
- long-term memory, 90, 503, 1124, 1170
- LORETA analysis, 18
- loss of consciousness, xvii, 155, 158, 159, 163, 164, 165

M

- machine learning, xvi, 99, 100, 101, 103, 106, 118, 120

NEW RESEARCH ON SIGN LANGUAGE

EDITOR: Reynard Louis

SERIES: Languages and Linguistics

BOOK DESCRIPTION: In this book, the authors present current research in the study of sign language. The opening paper concentrates on content structure in an example of formal Kenyan Sign Language discourse: a sermon.

SOFTCOVER ISBN: 978-1-53612-894-9

RETAIL PRICE: \$82

THE LANGUAGE OF PEDAGOGY TODAY: WHAT ARE THE NEW TEACHING CHALLENGES?

AUTHORS: Rebecca Soler Costa and Turgay Han (Faculty of Education, University of Zaragoza, Zaragoza, Spain)

SERIES: Languages and Linguistics

BOOK DESCRIPTION: The book is divided into two major parts. The first one provides an extensive and current theoretical framework on neologisms of a loan in the language of pedagogy: interlingual loans, voices of classical languages and inter-linguistic loans, with examples to facilitate their understanding.

HARDCOVER ISBN: 978-1-53613-129-1

RETAIL PRICE: \$160

SECOND LANGUAGE ACQUISITION: METHODS, PERSPECTIVES AND CHALLENGES

EDITORS: Doris Luft Baker, Ph.D. (Southern Methodist University, Dallas, Texas, US); Deni Lee Basaraba, Ph.D. (Data Analyst, Bethel School District, Eugene, Oregon, US)

SERIES: Languages and Linguistics

BOOK DESCRIPTION: Collectively, this book provides the most up-to-date review of our current knowledge about how the complexities of each of the linguistic registers across mathematics, science and social studies extends far beyond content-area vocabulary and warranting an intentional, purposeful focus on language, particularly academic English during content-area instruction.

HARDCOVER ISBN: 978-1-53614-305-8

RETAIL PRICE: \$230

NUMBER CONCEPTION AND APPLICATION

AUTHOR: Penglin Wang (Department of Anthropology and Museum Studies, Central Washington University, WA, US)

SERIES: Languages and Linguistics

BOOK DESCRIPTION: How number words came about? This book offers a trenchant answer to the question, explaining number conception and application slot by slot through a host of Eurasian languages. The cross-linguistic lack of width and depth in numeracy studies, which has existed for a long time, seemed impossible to overcome.

HARDCOVER ISBN: 978-1-63321-727-0

RETAIL PRICE: \$360
